HUGHES' COMPEND OF PRACTICE.

FIFTH PHYSICIANS' EDITION.

TO PHYSICIANS.

The several essential qualities which a good Visiting List should possess are, compactness, convenience of arrangement, and strength to resist the unusual hard wear it receives. These qualities are all combined in Lindsay & Blakiston's Physicians' Visiting List, which has now been published for forty-three years, and no better evidence of the practical worth of this book can be offered than the uniform increase in popularity it has enjoyed with each successive issue. One of its chief features is its size; it measures 61/8 x 37/8 inches, and the smallest size weighs but 31/2 ounces and is only 3/8 of an inch thick. The large sizes are a little thicker and heavier; it is, however, the smallest and lightest Visiting List published. Our many years' experience has enabled us to put it together in the best manner, and to add many improvements during the past few years. It is arranged for 25, 50, 75 and 100 patients per day or week, interleaved and plain, dated, undated and monthly. Prices range from 75 cents to \$3. Complete circular will be sent you upon application. P. Blakiston, Son & Co., Medical Publishers and Booksellers, 1012 Walnut Street, Philadelphia.

COMPEND

OF THE

PRACTICE OF MEDICINE

BY

DAN'L E. HUGHES, M.D.,

CHIEF RESIDENT PHYSICIAN PHILADELPHIA HOSPITAL; PHYSICIAN-IN-CHIEF, INSANE DE-PARTMENT, PHILADELPHIA HOSPITAL; LATE DEMONSTRATOR OF CLINICAL MEDI-CINE IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA; FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA, ETC.

FIFTH PHYSICIANS' EDITION.

THOROUGHLY REVISED AND ENLARGED.

INCLUDING A VERY COMPLETE SECTION ON SKIN DISEASES

AND

A NEW SECTION ON MENTAL DISEAS

PHILADELPHIA:
P. BLAKISTON, SON & CO

1012 WALNUT STREET.

1894.

Copyright, 1894, by P. BLAKISTON, SON & Co

PREFACE TO FIFTH EDITION.

The steady demand for the Compend of Medicine is practical evidence of its usefulness and has stimulated the author to make the fifth edition the most complete of any like book. It was not the original intention that it should in any way replace any of the textbooks upon the Practice of Medicine. It was written as a compend for the aid of the student, to be used in connection with a larger treatise. The book has however somewhat outgrown the original plan and I find a large number of Physicians use it. I have endeavored to make it more useful to them without affecting the arrangement which has made it so popular with the student. In the fifth edition the entire book has been thoroughly revised and the recent discoveries in the principles and practice of Medicine incorporated There has also been added a section on mental diseases, a subject daily forcing its importance upon the general practitioner. No medical student's education should be called complete without some knowledge of insanity, the increase of which is the alarm of the evening of the nineteenth century.

COMPEND

OF THE

PRACTICE OF MEDICINE.

INTRODUCTION.

The Principles of Medicine constitute what may be termed Medical Science.

The Practice of Medicine is the exercise of medical art, and embraces all that pertains to the knowledge of, prevention, and cure of the diseases for which the physician is called upon to direct treatment.

Disease may be defined as any departure from the normal standard of structure or function of an organ or tissue: Organic disease, when associated with an organic change in the affected part; Functional disease, when the abnormal phenomena are independent of any apparent structural lesion.

The study of disease, whether organic or functional in character, is termed *Pathology*.

Pathology explains the *origin*, *causes*, *clinical history*, and *nature* of the various morbid conditions which may disturb the economy.

The study of individual diseases constitutes *Special Pathology*, while the study of the morbid conditions common to a greater or less number of diseases constitutes *General Pathology*.

Nomenclature, or the naming of diseases, is a subdivision of gen-

9

eral pathology. The value of nomenclature as applied to disease is that the name chosen shall express the morbid condition involved, as well as its location.

If the morbid condition be an inflammation, the suffix *itis* is added to the anatomical name of the part affected; thus, if the disease be an inflammation of the peritoneum, it is termed *peritonitis*.

If the morbid condition is catarrhal, such as a transudation or flux, the liquid escaping upon a mucous surface, the suffix rhwa is used; thus, a catarrhal inflammation of the intestinal tract is termed diarrhwa and enterorrhwa.

If the morbid condition be a flow of blood or hemorrhage from a mucous surface, the suffix *rhagia* is used; thus, a hemorrhage from the small intestines is termed *enterorrhagia*.

If the morbid condition be pain without inflammation, the suffix algia is used. The various forms of neuralgiæ being an example, thus, neuralgia of the stomach is termed gastralgia.

If the morbid condition be in the blood, the suffix æmia is used. Thus, Anæmia is impoverishment of the blood; Uræmia, the morbid accumulation of urea in the blood; Septicæmia, putrid infection of the blood; Pyæmia, purulent infection of the blood.

If the morbid condition be in the urine, the ending *uria* is used to indicate it. *Albuminuria*, when albumin in the urine; *Hæmaturia*, when blood in the urine; *Oxaluria*, when oxalates occur in the urine.

If the morbid condition be a dropsical affection, the prefix *hydro* is added to the part affected. Thus, a dropsical accumulation in the peritoneum is termed *hydro-peritoneum*.

If the morbid condition be that of air in an unnatural part, the prefix *pneumo* to the name of the part is used, as in *pneumo-thorax*.

If the morbid condition be an inflammation of the membrane investing the part inflamed, the prefix *peri* is made use of. Thus, for an inflammation of the investing membrane of the kidney the term is *perinephritis*.

Inflammation of the connective tissue surrounding an organ is designated by the prefix para. Thus, parametritis for inflammation of the connective tissue about the womb.

A termination in *oma* signifies a tumor, as in *sarcoma* or *carcinoma*. The suffix *pathy* is used to designate a morbid condition of a part, without indicating its particular character, an example being the use of the term *encephalopathy*.

Morbid Anatomy, or pathological anatomy, is the study of the changes in the tissues and fluids of the body appreciable to the naked eye or with the aid of the microscope.

Histology is the study of the minute anatomy of the tissues and fluids of the body with the microscope.

Pathogenesis is the study of the origin and development of pathological processes.

Lesions (lado, to hurt) are appreciable anatomical changes.

Etiology is that subdivision of general pathology which treats of the causes of disease. The knowledge of the cause of any morbid action is of value in the prevention, management, and removal of disease.

The Causes of disease may be divided into internal, external, ordinary, specific, primary, secondary, predisposing, and exciting.

Examples of *internal* or *intrinsic causes* are those having their origin in the mind, such as prolonged mental application, intense or long-continued emotional excitement, long-continued mental depression, and the possession of and concentration upon a predominant idea. Other examples are the accumulation of certain products in the blood, such as urea, uric acid, or lacid acid.

External or extrinsic causes are such as infectious miasms, viruses, poisons, wounds, and injuries.

An *ordinary cause* is one to which all are more or less exposed, such as atmospherical changes.

Specific or special causes are those producing a distinct and specific disease, such as the bacillus tuberculosis, causing Tuberculosis; comma bacillus. Asiatic Cholera: oscillaria malariæ. Malaria.

A contagious disease is one whose causative agent is a specific poison that, introduced into the system of another, will give rise to the same disease. An infectious disease is also due to a special cause that under certain conditions is capable of unlimited increase or multiplication. An infectious disease may or may not be contagious.

An example of a primary cause is any external traumatic injury.

A secondary cause is well seen in the secondary pericarditis resulting from an accumulation of urea in the blood, the retention of the urea in the blood being due to a diseased kidney.

A predisposition to disease is a special liability or susceptibility to its occurrence, and may be either inherited or acquired.

Inherited or constitutional predisposition to certain diseases is also

termed *Diathesis*; an example is in the offspring of phthisical parents, who are said to be of a *phthisical diathesis*.

Acquired predisposition is such as arises from—

- Habits: Strain upon the nervous system resulting in nervous diseases, or the changes resulting from alcoholic and other excesses.
- II. Age: Children are very liable to catarrhal disorders. Young adults, to fevers and perverted sexual disorders.

Middle age, to heart, kidney, and digestive disorders, and cancer.

Old age, to degeneration of the heart and vessels.

- III. Occupation: Miners, weavers, and cutlers, lung diseases, or painters and printers to lead colic.
- IV. Sex: Women, emotional nervous diseases.

Men, as more exposed, rheumatism and pneumonia.

V. Race: Negro, phthisis and scrofula; often exempt from malaria.

Exciting causes are those giving rise to morbid conditions in those already predisposed to certain diseases, but lacking the action which determines their occurrence; to wit: persons predisposed to acute rheumatism, on being exposed to certain atmospheric changes have an attack; fear has produced chorea; anger has caused jaundice; worry has produced cardiac troubles.

The Clinical History of disease includes all the symptoms and signs which may occur from the *period of incubation* until its final *termination*.

Symptomatology is the study of the signs and symptoms of disease or such alterations in the healthy functions giving evidence of the existence of a diseased condition or perverted function. Symptoms may be either subjective or objective. Objective, when evident to the senses of the observer, as redness, swelling, high temperature, or disorders of locomotion. Subjective, when felt or known only by the patient, such as pain, numbness, vertigo, or nausea.

Physical signs are, strictly speaking, objective symptoms, requiring for their elucidation special methods, such as *inspection*, *mensuration*, *palpation*, *percussion*, and *auscultation*. These are chiefly used in examinations of the chest and abdomen.

Associated with the study of symptomatology should be considered the complications and sequelæ of disease.

Complications are certain conditions which may arise in the course of the original disease, but are not regarded as a necessary accompaniment of the disease; thus hemorrhage from the lungs or hæmoptysis is a complication of tuberculosis; intestinal hemorrhage, the most frequent complication of typhoid fever.

Sequelæ (sequor, I follow) are the morbid phenomena left as a result of a disease; thus, valvular disease of the heart often results from an attack of acute articular rheumatism.

The Period of Incubation is that interval between the entrance of a poison into the system and the manifestation of the symptoms.

The Prodromes are the earliest recognizable symptoms; as the rigors or chills during the invasion of fever, and the various aura preceding an epileptic attack.

An acute disease is one in which the invasion is sudden and rapid, and as a rule severe; when the symptoms develop less rapidly and are less intense the disease is said to be *sub-acute*; when gradual or slow in development, duration, and intensity, the disease is said to be *chronic*. It must be borne in mind, however, that there may be disturbed action in every intermediate degree between these extremes.

Pathognomonic is the term applied to such symptoms as belong to one particular disease, and are therefore characteristic of it, thus, the rusty sputum of pneumonia, the eruption of variola.

The Termination of a diseased action may occur in one of three ways, to wit: Cure, Secondary Processes, or in Death.

Cure may occur by-

- I. Lysis, or slow return to health.
- II. Crisis, abrupt termination, usually with a critical discharge.
- III. Metastasis, or changing from one location to another.

Secondary processes is when the diseased action is substituted by a new morbid process, to wit: Rheumatism followed by endocarditis; apoplexy by cerebral softening.

By Death is meant a complete cessation of tissue change occurring by

- I. Asthenia, or an ever increasing debility, to wit: phthisis, cancer, Bright's disease.
- II. Anamia, or insufficient quantity or quality of blood.
- III. Apnæa, or non-aeration of blood, to wit: acute lung diseases or croup.

IV. Coma, death beginning at the brain, to wit: uræmia, narcotic poisoning, cerebral hemorrhage.

Diagnosis of disease, or the discrimination of diseases, implies a complete, exact, and comprehensive knowledge of the case under consideration, as regards the origin, seat, extent, and nature of all its morbid conditions

A direct diagnosis is made when the morbid condition is revealed by a combination of clinical phenomena, or some one or more pathognomonic symptoms.

A differential diagnosis is the result when the diseases resembling each other are called to mind and eliminated from each other.

A diagnosis by exclusion is by proving the absence of all diseases which might give rise to the symptoms observed, except one, the presence of which is not actually indicated by any positive symptoms.

Prognosis of disease is the ability or knowledge to foretell the most probable result of the condition present, and involves an amount of tact or knowledge only acquired by prolonged clinical experience.

Treatment. The ultimate and most important object in the study of medicine, from a practical point of view, is to be able to cure, relieve, or prevent disease. This does not consist solely in the administration of drugs, but requires strict and faithful attention to diet and hygiene.

When the object is to prevent disease, such as smallpox by vaccination, it is called *Prophylactic or Preventive* treatment.

When disease is to be broken up, although already begun, such as aborting the chill of malaria, it is called the *Abortive* treatment.

When the disease is allowed to run its natural course without attempting its removal, but being constantly on the alert for obstacles to its successful issue, such as the generally adopted plan of treating continued fevers, it is called *Expectant* treatment.

When the disease is incurable, and removal of marked suffering is the object, it is called *Palliative* treatment.

When marked weakness and prostration are to be overcome, it is called *Restorative* treatment.

FEVERS.

Fever is a condition in which there are present the phenomena of rise of temperature, quickened circulation, marked tissue change, and disordered secretions.

The *primary cause* of the fever phenomena is still a mooted question, and is either a disorder of the sympathetic nervous system giving rise to disturbances of the vaso-motor filaments, or a derangement of the nervous centres located adjacent to the corpus striatum, which have been found, by experiment, to govern the processes of heat production, distribution, and dissipation.

Rise of temperature is the preëminent feature of all fevers, and can only be positively determined by the use of the clinical thermometer. The term feverishness is used when the temperature ranges from 99° to 100° Fahr.; slight fever if 100° or 101°; moderate, 102° or 103°; high if 104° or 105°; and intense if it exceed the latter. The term hyperpyrexia is used when the temperature shows a tendency to remain at 106° Fahr, and above.

Quickened circulation is the rule in fevers, the frequency usually maintaining a fair ratio with the increase of the temperature. A rise of one degree Fahr, is usually attended with an increase of eight to ten beats of the pulse per minute.

The following table gives a fair comparison between temperature and pulse:—

A	tempera	ture	of 98°	F.	corresponds	to a	pulse of	60
	6.6	6.6	99°	F.	6.6	64	6:	70
		6.6	1000	F.	6.	- 6	66	80
	14	4.6	ioio	F.	6.6	6.6	.6	90
	64.	4.6	102°	F.	6.6	6.6	66	00
	6.6	6.6	103°	F.	-6	6 -	6.	110
	£÷.	6+	104°	F.	4.6	6 6	+6	20
	6.	.6	105°	F.	46	64	+4]	130
	66	6.5	106°	F.	6.6	6.0	66]	40

The tissue waste is marked in proportion to the severity and duration of the febrile phenomena, being slight or nil in febricula, and excessive in typhoid fever.

The disordered secretions are manifested by the deficiency in the

salivary, gastric, intestinal, and nephritic secretions, the tongue being furred, the mouth clammy, and there occurring anorexia, thirst, constipation, and scanty, high-colored, acid urine.

GENERAL TREATMENT OF FEVERS.

- 1. Reduce the temperature. The cold bath or cold pack will do this most decidedly, but entails much labor, and is not altogether free from danger, and so its use is advised only in proper cases. Cool sponging is of decided value. *Quinina*, in gr. xx doses repeated, rarely fails. *Antipyrine*, gr. xx repeated, and *antifebrin*, gr. x-xv repeated, are also recommended, but their tendency to depression must be watched.
- 2. Lessen the circulation. If the pulse be full, strong, and rapid, use aconitum, or veratrum viride. If the circulation be weak, stimulants with digitalis or caffeina are indicated.
- 3. Attend to the secretions. Remove the waste of the tissues by diuretics, diaphoretics, and, if particularly indicated, laxatives. It is better for every fever that the skin should be moist, than that it should be harsh and dry. It is better that the urine should be abundant, than that it should be scanty and thick with tissue waste. Watch the stools that you may judge whether the food, be it solid or liquid, is being digested. The free use of water is beneficial in promoting the various secretions.
- 4. Nourish the patient. "Don't starve a fever." Administer milk, beef-tea, animal broths, peptonized and other light nutritious food, in small quantities, but at frequent intervals.

Alcohol is only indicated in long-continued fevers or those of asthenic type. Check or discontinue alcohol when its odor is noticeable on the breath.

5. Watch the nursing. Much of the success in the management of fever patients can be attributed to good, sensible nursing. Through it are secured the five important essentials of every sick-room; to wit: cleanliness, cheerfulness, regularity, ventilation, and light.

CONTINUED FEVERS.

All continued fevers are characterized by a steady progress of the febrile movement, without either a too decided rise or fall in the temperature to modify the impression of a continuous action.

SIMPLE CONTINUED FEVER.

Synonyms. Irritative fever; febricula; ephemeral fever; synocha. Definition. A continued fever, of short duration, mild in character, not the result of a specific poison, rarely fatal, but when death does occur, presenting no characteristic lesion.

Causes. Fatigue, mental and physical; exposure to the sun, great heat or cold; excesses in eating and drinking resulting in an attack of indigestion; excitement and violent emotion. Most common in childhood. It is not a miasmatic fever, neither is it contagious.

Symptoms. Onset sudden with an abrupt feeling of lassitude, followed by a decided chill or chilliness, a sudden and rapid rise of temperature, quick, tense pulse, headache, dry skin, great thirst, coated tongue, costive bowels, and scanty, high-colored urine. Cases due to errors in diet are accompanied by nausea and vomiting. Attacks occurring during childhood, due to excitement, fright, or the emotions, may be associated with convulsions. The temperature may within an hour or two reach 103° F., or more, when slight delirium may occur. The affection has no constant or characteristic eruption.

Duration. From twenty-four hours to six or seven days.

Termination. Usually within a few hours, to a day or two, the temperature rapidly falls to the norm, an instance of *crisis*; or it may continue for several days, gradually falling to the norm (*lysis*). *Herpes* about the lips and nostrils are often observed at the close of an attack. *Convalescence* is rapid.

Diagnosis. Unless the fever can be attributed to some one of the causes that give rise to it, a doubt as to its character may exist for the first twenty-four hours, after which time it can hardly be mistaken for any other disease.

The following is a familiar instance of this affection. A child, apparently in the best of health, at play, or, may be, at school, suddenly complains of nausea and may vomit, the skin becoming hot, dry, and flushed, or soon covered with an erythematous rash; the pulse is quick and tense, there is headache, pains in the limbs, and great fretfulness or nervousness. The axillary temperature may reach 102°-104° F. The whole aspect is most alarming. A laxative is administered, the surface sponged with a tepid lotion, sleep follows, during which there may be free perspiration, and the following day the child is and continues perfectly well.

Prognosis. Recovery, without sequelæ, the rule.

Treatment. Rest in bed. If evidences of gastro-intestinal disorder be present, order a dozen or more powders containing hydrargyri chloridi mite, gr. ½; sodii bicarbon., gr. ij; pulv. ipecac, gr. ½, one every two hours; some hours after the last powder has been taken, an enema or a seidlitz powder. Much comfort follows sponging the surface with tepid or cold water and the use of saline diaphoretics and diuretics. If the pulse be very quick, add small doses of aconitum. Cases not associated with digestive disorder have the fever and nervous symptoms relieved by acetanilidum, gr. ij-v, according to age, every two or three hours. Liquid diet is most palatable. Cases in which nervous symptoms or insomnia are prominent should have a few doses of potassii bromidum during the day, or a bedtime dose of trional, gr. v-xx. During convalescence tonic doses of quininæ sulphas or tinctura nucis vomicæ.

INFLUENZA.

Synonyms. La grippe; grip; contagious catarrh; epidemic catarrhal fever.

Definition. An acute, specific, infectious fever, moderately contagious; sporadic, epidemic, and pandemic; associated with catarrhal inflammation of the respiratory tract, sometimes of the digestive, always accompanied with disturbances of the nervous system and a *debility* out of all proportion to the intensity of the fever and the catarrhal processes and apt to be attended with serious complications and sequelæ.

The disease was almost unknown upon the appearance of the pandemic in the winter of 1889-90.

Causes. A specific poison, the *bacillus of Pfeiffer*, which is uninfluenced by soil, climate, season, or atmospheric changes. The mode of development of the remarkable outbreaks of influenza is not yet understood. One attack rather predisposes to another attack.

Morbid Anatomy. There are no characteristic anatomical lesions.

Symptoms. The clinical history of this disease presents the greatest variations as regards intensity, from the most trifling indisposition in one, to an illness of the gravest kind, terminating in death, in another.

The onset is, in the majority of cases, sudden, with a chill followed

by fever, the temperature reaching 101° to 103°, a quick, compressible pulse, and severe shooting pains in the eyes and frontal sinuses and myalgic pains in the joints and muscles. The chill and fever are rapidly followed by chilliness along the spine, pain in the throat, hoarseness, deafness, coryza, sneezing, injected, watery eye, and a dry, irritative, laryngeal cough, sometimes becoming bronchial. The tongue is furred, there is anorexia, epigastric distress, nausea, voniting, and oftentimes diarrhaa. In some instances the digestive symptoms are the most prominent, when dysentery may occur. Associated with either the respiratory or digestive form of attack may be marked disturbances of the cerebro-spinal functions, or these latter may be the most prominent symptoms present.

The above symptoms are always associated with depression of spirits, and a *debility* altogether out of proportion to the intensity of the fever and the catarrhal phenomena. Delirium is rare, but marked *hebetude* and *cutaneous hyperæsthesia* are common.

Duration. The fever declines in from four to seven days, when begins a protracted convalescence. Relapses frequently occur, and second, third, or even more numerous attacks in the same individual may be observed, the susceptibility of the system after an attack being remarkable.

Complications. The most frequent are those associated with the respiratory organs. Severe bronchitis, associated in the feeble or aged with fever, typhoid delirium, and tendency to ædema of lungs. Croupous and catarrhal pneumonia are frequent and fatal complications. Cerebro-spinal meningitis also noted.

Sequelæ. A persistent headache; neuralgia; neuritis; insomnia; melancholia; mania; enlargement of lymphatic glands. The great increase in pulmonary phthisis since the pandemic of 1889-90 is more than a coincidence.

Diagnosis. Isolated cases may be mistaken for a "bad cold." But when epidemic, the *sudden onset, marked general catarrh*, and *decided prostration* should prevent error.

At the onset of an epidemic Dengue will be remembered. Cerebro-Spinal Fever has many symptoms in common with the nervous form of influenza.

Prognosis. Recovery is the rule when it occurs in the healthy and vigorous, according to Pepper less than one-half of one per cent. die. *Grave* when the very young, the very old, or those suffering from

Or-

organic disease, such as Bright's disease, fatty heart, emphysema, or the tubercular diathesis, are attacked.

Treatment. No specific. During the prevalence of the epidemic influence exposure to cold should be avoided. Support the system and pursue a purely symptomatic method of medication. All measures, of whatever kind, which tend to depress the general nervous system, or the functional activity of the respiration, and especially the heart-power, are to be avoided. Patients should be kept in bed until fever declines or longer.

The catarrh, pains, and cough are at least ameliorated by the following:—

R.	Pulvis ipecacuanhæ Potassii nitrat.,						
Ever	y three hours.					0	

R. Phenacetin, gr. iij
Pulv. camphoræ, gr. j
Caffeina citrat., gr. j.

Every two or three hours.

During the last pandemic the disease was frequently aborted in those of vigorous health by a few ten or fifteen grain doses of antipyrine, although in those of feeble resisting power much harm resulted from the indiscriminate use of this drug. Dr. Roland G. Curtin warmly recommends salicinum as coming "as near to being a specific as we can get with the drugs now in our possession." Quinina in full doses at the very onset often aborts the disease.

I have seen excellent results in neuralgic cases with cinchonidinæ salicylas, gr. v every four hours.

The frequent inhalation of *tincturæ benzoin comp.*, 3ss-j, in *aquæ bul.*, Oj, relieves the naso-pharyngeal and bronchial catarrh.

If the bronchial symptoms become troublesome, use-

	* *							,	
R.	Ammonii muriat., .							. grs. x	
	Strychninæ sulph.,							. gr. 15	
	Syr. ipecac.,						,	. m v	
	Spts. frumenti,	٠		٠	٠			f 3 ss	
	Aquæ chloroformi,			٠				. 3 iss. M	
p. r.								**	

The complication of *pneumonia* requires prompt stimulating treatment. Dr. Pepper recommends *strychninæ sulph*, in full doses as

the most important remedy against this complication, and suggests the following combination as often valuable:—

R.	Morphinæ sulph.,									
	Quininæ sulph., .			4	-				. gr. xxxvj	
	Strychninæ sulph.,								. gr. ss	
	Acid. phos. dil.,				٠.				f z iij	
	Glycerini,								f 3 v	
	Aquæ.,					q.	S.	ad	f 🖁 iij.	M.

S. A teaspoonful four to six times daily, in water.

During convalescence administer *strychninæ sulph.*, gr. $\frac{1}{48}$, four times daily.

Always have in mind that influenza is often the exciting cause of a phthisical development in those so predisposed.

TYPHOID FEVER.

Synonyms. Enteric fever; gastric fever; nervous fever; enteromesenteric fever; abdominal typhus; autumnal fever.

Definition. An acute, self-limited, infectious *febrile* affection, due to a *special poison*; characterized by insidious prodromes; epistaxis; dull headache followed by stupor and delirium; red tongue, becoming dry, brown, and cracked; abdominal tenderness, early diarrhæa, and tympany; a peculiar eruption upon the abdomen; rapid prostration and slow convalescence; a *constant lesion* of Peyer's patches, the mesenteric glands, and of the spleen.

Causes. Predisposing and exciting.

The chief predisposing causes are Age and Season. It is claimed by Pepper that a particular susceptibility exists in certain individuals and families to typhoid fever.

The most frequent age is between fifteen and thirty years, and cases are rarely seen in those of forty-five years and over. I have seen well-marked cases with typical symptoms at eighteen months and at five years of age. The autumn months show the most cases, and particularly following a hot and dry summer.

The exciting cause is a special typhoid germ, the bacillus of Eberth.

The poison usually results from the decomposition of the typhoid stools and the sputum, although it has been claimed that the disease may be generated under certain undetermined circumstances, de novo, from ordinary filth and decomposition.

The atmosphere is never impregnated with the fever germ. The poison gains its entrance into the system by means of infected water, milk, ice, meat, or other food. The germ is easily destroyed by thorough disinfection of the stools and sputum with heat, mercuric bichloride, or acidum carbolicum, but it is to be borne in mind that extreme cold will not destroy the typhoid germ.

Pathological Anatomy. The specific anatomical lesions of typhoid fever are invariably present, and are so characteristic that an examination of the body after death will in any case make known the nature of the disease, even had the symptoms been unknown. These lesions consist in changes in the *Peyerian patches* and *solitary glands*, which may be divided into well-defined stages, as follows:—

First. Stage of Infiltration, or Swelling from infiltration and excessive proliferation of their cellular elements: the surrounding mucous membrane is also infiltrated with cells. The Peyer's patches are thickened, hardened, and elevated above the mucous membrane. The number of patches and glands involved is from three or four up to nearly the entire number. The above changes have been noted as early as the second day.

Second. Stage of Necrosis, Softening, or Sloughing of the solitary and agminate glands. Not all the patches necessarily slough; in a certain number of them the morbid changes are arrested before softening. This stage constitutes the anatomical changes of the second and third week.

Third. Stage of Ulceration following and depending directly upon the softening and sloughing, the sloughs gradually separating, beginning at the periphery of the swollen gland and finally, at about the end of the third week, become detached, leaving ulcers of various sizes.

Fourth. Stage of Cicatrization, or in rare cases perforation. The ulcer gradually diminishes in size, the surface becoming covered with a delicate layer of granulations, which is soon transformed into connective tissue and covered with epithelium, the resulting scar being slightly depressed. The gland-structure is never regenerated.

The Mesenteric glands become infiltrated, enlarged, and softened, but seldom ulcerate.

The Spleen also enlarges and softens, the increase in size beginning in the middle of the first week, reaching its height at the end of the second week, the organ being twice or three times its normal size.

There are, besides, parenchymatous degenerations, or granular changes in all the tissues of the body.

Symptoms. Stage of Prodromes.—The onset is insidious, with a feeling of general malaise, vertigo, headache, particularly occipital pain, disordered digestion, disturbed sleep, epistaxis, depression, and muscular weakness, followed by a chill or chilliness, the patient being unable to designate the day when the symptoms began. In rare instances the disease begins abruptly with a chill, followed by high fever; this is particularly the case in malarial districts.

The exact duration of these premonitory symptoms is not known, and may be said to vary from a few days to two or three weeks.

First Week, dates from onset of the fever, when are present increasing temperature, frequent pulse, headache, listlessness, the eyes closed as if asleep, coated tongue, nausea, diarrhwa (there may be constipation), the abdomen moderately distended and, upon pressure in the right iliac fossa, gurgling sounds and tenderness. Upon the seventh day a few reddish spots resembling flea bites appear upon the abdomen, chest, or back.

Second Week. The foregoing symptoms are exaggerated; fever continuous, frequent and compressible and dicrotic pulse, tympanitic, tender abdomen, gurgling in the right iliac fossa, nocturnal delirium, severe and constant headache, often stupor, a short cough with distinct bronchial râles on auscultation, irregular muscular contractions (subsultus tendinum), sordes upon the teeth and lips, the tongue loses its coating and becomes more or less dry, the diarrhwa continuing. During this stage deafness develops, often increasing until profound, and continuing into convalescence. Disturbances of vision are frequent in pronounced cases. The spleen increases in size.

Third Week. Fever changes from continuous to remittent; the evening exacerbations continue as high as the preceding week, the morning fall growing more decided each day, but all the other symptoms remain about the same until near the end of the week, when a marked amelioration begins.

In a fair proportion of cases all the symptoms grow worse toward the end of the second or during the third week. The *prostration* is extreme, the *stupor* so marked that it is hardly possible to rouse the patient, the *tongue dry*, *hard*, cracked, and covered with a *brown crust*, *sordes* collect on the gums, teeth, and cracked lips, the *pulse* rapid and feeble, the *respirations* shallow and quickened, *retention*

of urine, which contains albumin, and the stools voided involuntarily, and bedsores developing, this condition terminating in death,

or passing thus into the fourth week.

Fourth Week. The fever decidedly remits; almost normal in morning, the pulse becoming less frequent and more full, the tongue gradually becoming clean, the abdomen lessens in size, the diarrhæa ceases, the patient passing into a slow convalescence, greatly emaciated, which condition may continue for several weeks.

Analysis of Symptoms. The temperature record of typhoid fever is characteristic. The fever on the morning of the first day may be stated at 98.5° F., evening 100.5°; second morning 99.5°, evening 101.5°; third morning 100.5°, evening 102.5°; fourth morning 101.5°, evening 103.5°; fifth evening 104.5°. From that time until end of the second week, the evening temperature ranges between 103° and 105°, the morning temperature being a degree or more lower. During the second or third week hyperpyrexia, or fever above 105° F., may develop and adds to the gravity of the attack. A high temperature during the third and fourth week is of grave import.

Diarrhæa is the principal intestinal symptom; if absent, the lesion is slight. The stools are at first dark, but early in the second week they become fluid, offensive, ochre-yellow in color, resembling "pea soup," and may be streaked with blood. They number from three to fifteen in the twenty-four hours.

Constipation occurs more frequently than is supposed. I have seen fifty cases with constipation within the past five years.

The urine has the ordinary febrile characters. Retention is very common. Ehrlich describes a reaction which he believes is rarely met with save in typhoid fever. In examinations of the urine by Ehrlich's diazo-reaction in fifty cases of typhoid fever in the wards of the Philadelphia Hospital the reaction was found in thirty-eight. It has also been found in a number of other conditions, particularly those having gastro-intestinal symptoms.

Eruption is almost constant. Consists of from five to twenty small, rose-colored spots on the abdomen, chest, or back, sometimes on the limbs, appearing in crops, lasting about five days, disappearing on pressure and at death. Returning with relapses. Eruption day from the seventh to the ninth.

Rarely spots of a delicate *blue* tint—the "taches bleuâtres" of French authors—are observed.

Nervous symptoms are, pronounced headache, early and severe, dullness of intellect soon following, passing into drowsiness and stuper, with great prostration. Deafness pronounced. Sight impaired, in grave cases double vision. Delirium low and muttering, generally pleasant in character; always present in marked cases. Coma vigil is a grave symptom, the patient lying perfectly quiet with eyes open, taking no heed to his surroundings.

Muscular symptoms are developed late in the second or early in the third week, and consist of irregular contractions or subsultus tendinum, and are the result of the great debility. The reverse of muscular contractions, to wit, perfectly motionless in bed, attempting no muscular effort of any kind, is a grave sign.

Convalescence shows great debility and emaciation, great anæmia, and great nervousness often very protracted. It is during convalescence that great irritability of the heart, profuse night sweats, and insomnia occur, and in women loss of hair.

Complications. Intestinal hemorrhage is the most frequent and at times the most critical of any of the complications of typhoid fever. The hemorrhage may occur any time between the fourteenth and twentieth day; a sudden decline of the temperature to the norm or below frequently precedes the passage of blood by stool. The hemorrhage is due to the erosion of a vessel during the ulcerative action.

Perforation makes the case almost hopeless. Peritonitis without perforation adds to the gravity, but not necessarily fatal. Lobar pneumonia, hypostatic congestion, and bronchitis are frequent occurrences. Albuminuria and acute nephritis may occur, as may phlegmasia dolens. Bedsores are frequent, resulting from the impaired nutrition, emaciation, and pressure over bony prominences, and the difficulty of keeping patient clean.

Ulceration of tongue and mucous membrane of cheek is sometimes seen.

Sequelæ. Paralysis—either mono- or paraplegia—due to an acute neuritis. Post-febrile insanity occurs more frequently after typhoid than any other febrile condition, save perhaps influenza. Acute Nephritis associated with ædema. Alopecia complete or partial. Trans-

verse markings of the nails. Tuberculosis may develop in those predisposed.

These sequelæ of typhoid fever are all the result of the impaired nutrition and great prostration.

Relapses are common. The symptoms all return abruptly; the duration is half the time of the original attack; occur at the end of the fourth or beginning of the fifth week. Not so fatal as generally supposed.

Abortive typhoid fever are cases of mild character, having many of the typical symptoms, running its course in about two weeks. The so-called walking cases are often of this character.

Diagnosis. An error that is constantly being made is that of confounding typhoid fever with the typhoid (depressing) symptoms or condition developing during the course of many acute diseases. The absence of the characteristic diarrhwa, the peculiar cruption, and the typical temperature record should prevent the error.

Enteritis has intestinal derangement and fever alone.

Peritonitis, abdominal symptoms only, with constipation.

Acute miliary tuberculosis often mistaken for typhoid fever, an error difficult to prevent at times.

Meningitis lacks the intestinal symptoms and fever record.

The so-called *typho-malarial* or *malario-typhoid* fever has many symptoms in common, but lacks the diarrhœa, eruption, and temperature record.

Prognosis. A positive prognosis cannot be made. Favorable indications are constipation, slight diarrhæa, low temperature, and moderate delirium. Unfavorable symptoms are obstinate and severe diarrhæa, early high temperature, marked nervous symptoms with coma vigil or stupor, albuminuria, and repeated intestinal hemorrhages.

The prognosis is always more favorable in winter than in summer. When death occurs it is usually during or about the third week, the result of exhaustion, cardiac failure, or some complication.

The *mortality* in typhoid fever in private practice is about one death in twenty; in hospital practice it varies from one death in five to ten cases, although the cold-bath treatment has greatly reduced the hospital mortality.

Treatment. There is no specific treatment for typhoid fever.

The indications are to sustain life and meet the urgent and dangerous symptoms as they arise.

Flint held that, as it was a self-limited disease, "if the patient can be kept alive, after three, four, or more weeks, recovery will take place provided there be no serious complication. In a case of severe uncomplicated fever the patient is in a situation not unlike that of a person in danger of drowning not far from or perhaps very near the shore. If he drown it is because his strength gives way before the shore is reached. As a person in this situation requires only to be buoyed up by some support, so the fever patient in a similar emergency may only need supporting measures to live."

It is important to secure intelligent *nursing*, a quiet, airy sick-room with an average temperature of 65° Fahr., and the most scrupulous *cleanliness* of patient, bedding, and utensils. The patient must go to bed from the first moment of suspicion that typhoid fever is developing, and remain in bed until convalescence is well established.

The *stools* and *urine* must be *disinfected* the moment voided, and quickly discharged into a sewer or buried.

The diet should be nutritious and liquid at intervals of every two or three hours. Diluted milk is the best article, but broths, soups, liquid peptonoids, coffee, and cold milk and tea may be alternated. A word of caution, however, as to the quantity of food administered. The amount should be small, as the digestive capacity of the patient is greatly lessened by the febrile phenomena. Much harm results in typhoid fever from stuffing the patient.

The tendency to bed-sores must be borne in mind and treated. The use of finely powdered boric acid over irritated parts will often prevent the development of sores.

Attention should be given to the mouth, and the dryness and tendency to collection of sordes prevented by frequently washing the mouth with glycerine and water or weak boric solution.

The following remedies have advocates, claiming that they modify the course of the disease; hydrargyrum, iodum, acidum carbolicum, mineral acids, argentum nitras, and ergota.

A mild case of the disease will do well with acidum hydrochloricum dilutum, mx-xx, well diluted, every four hours, alternated with quininæ sulphas, gr. ij. Cases with high temperature and costive bowels are sometimes wonderfully benefited by the following:—

R.	Hydrargyri chlor. mite,		à				gr. 1/4-1/2
	Pulv. ipecacuanhæ,						gr. 5
	Pulv. opii,					۰	gr. 🕏
	Sodii bicarb						gr. 1

Repeated every three or four hours, and quining sulphas, gr. ij, every four hours.

The present so-called "specific treatment" of this disease consists in the administration every second evening, until four doses are taken, of *hydrargyri chloridi mite*, gr. vij-x, which seemingly lessens the frequency of the stools in the later stages of the attack, although slightly increasing them at the time. Also administering from the beginning of the attack—

Sig.—One, two, or three drops in ice water, every two or three hours, after food.

The reduction of temperature is one of the most important indications in the majority of cases of typhoid fever. There is now no doubt that the former views regarding the amount of fever a patient could stand for one or two weeks are responsible for the high mortality in this disease. A temperature of 103° to 105° for a dozen days is dangerous and should be combated. Among the measures that have been used are the calomel powders mentioned above, or antifebrin, gr. iii, every two hours in the afternoon until 102° is reached or phenacetin, gr. x, repeated in three or four hours, or quininæ sulphas. gr. xv-xx, morning and night. A strong prejudice has arisen against quinina within the last few years, nevertheless, I know I have seen great benefit from its use, and strongly recommend it. Cold sponging with water alone or alcohol and water is often of great value in mild cases. The cold pack is a very powerful antipyretic and, in cases with temperature of 104° or 105°, in which the cold bath cannot be employed. can be made use of. The bed should be protected by a rubber cloth, and the patient, with his clothing removed, should be wrapped in a sheet wrung out of cold water. The surface should be rubbed briskly through the sheet, and from time to time cold water is freely sprinkled of sheet. Friction must be continued during the pack.

and ice cloths or cap placed on the head. The duration of the cold pack is determined by the temperature and the reactive powers of the patient. It is often well to administer an alcoholic stimulant or a hypodermic injection of strychninæ sulphas before the pack and, may be, after.

The cold bath after the method of Brand, or "tubbing," has proven most prompt and decided for reducing temperature. It consists in the systematic employment of general cold baths with frictions whenever the temperature reaches 102.2° F. As often as the temperature, taken every three hours in the mouth or rectum, is over 102.2°, the patient receives a bath lasting fifteen or twenty minutes. He wears a thin muslin garment or, wrapped in a sheet, he is given a stimulant and carefully lifted into the bath of 65° or 70°, some cold water being poured over his head and shoulders to lessen the shock: the head rests on an air pillow, the body submerged to the neck. During the whole period of the bath the patient must be briskly rubbed. The friction and affusion are of value in preventing chill and cyanosis. After the bath the wet linen is quickly removed and the patient placed in bed, wrapped in dry sheet, and covered with a blanket. A stimulant is again given after the bath and if tendency to cyanosis or heart failure a hypodermic injection of strychnina. The temperature is taken after patient is placed in bed and again in half to three-quarters of an hour, and if not then 102° is not again taken for three hours. The good effects of the bath are, reduction of temperature, with the intellect clearer, the stupor lessens, the muscular twitchings diminish, insomnia overcome, sleep usually following a bath, and a general stimulating effect upon the heart and nervous system.

Diarrhwa should not be checked unless it exceeds three or four stools in twenty-fours, when may be used—

R.	Bismuth subnit.,						, gr. xx	
	Acid. carbol.,							
	Tinct. opii deodorat.,	, .					. gtt. x-xv	
	Mucil. acaciæ,							
	Aquæ,							M.
G.—Ev	ery three or four hour	s.						
Ŗ.	Cupri sulph.,						. gr. ½	
	Extracti opii,				a-		. gr. ¼.	Μ.
s.—In	pill, every four hours.							

Sig Or-

Or— R. Salol,					М.
Or— R. Acid. sulph. aromat., Tinct. opii deodorat., . Sig.—In water every three hours.					М.

For *Tympanites*: cold compresses or an ice bag to the abdomen. Rarely, a turpentine stupe is of value. Page recommends the gentle introduction of a catheter far up the rectum to relieve a powerless bowel, as urine is drawn from a paralyzed bladder. Tympany with constipation is relieved by the use of *olei terebinthinæ*, gtt. x, *olei ricini*, gtt, xv, in emulsion every three or four hours.

For *Thirst*: cooling drinks in moderation, or pellets of ice slowly dissolved in the mouth.

Headache: cold to the head, mustard to the neck, and foot baths: if these fail to relieve, morphina or atropina hypodermically.

Delirium: if from debility, increase the stimulants; other causes, use morphina, if active.

Insomnia, if of long duration, use trional gr. xv-xxx.

Restlessness and coma vigil, stimulants, and ice cap.

Debility: food every two or three hours; do not permit sleep to interfere with nourishment. Stimulants are indicated early, the best guide being the heart's action; an average amount would be \mathfrak{F}_{v} spts. vini gallici, per diem, or chloroformi, \mathfrak{m}_{ij} -v, every hour or two, well diluted, or moschus, gr. x, repeated p. r. n.

The bladder should be examined at each visit.

Intestinal hemorrhage: at once morphina, gr. ¼, hypodermically, and ext. crgotæ fld., f3j, repeated p. r. n., or Monsell's solution, gtt. ij-iv, every two hours, or acidum tannicum. gr. ij-v, with pulv. opii et ipecacuanhæ, gr. iij every hour, and cold to abdomen.

Perforation and peritonitis: at once morphina sulphas, gr. ½, hypodermically, followed with extractum opii, gr. j every hour, hot applications to the abdomen and bold stimulation.

Lobar pneumonia and bronchical catarrh: dry cups and the use of the following:—

M.

Ŗ.	Ammonii muriat,											. Zii.
	Strychninæ sulph.,											or I/
	Spts. chloroformi,		٠								٠.	· 3 jss.
	Aq. lauro-cerasi,								q.	S. :	ad.	f Ziv.
SIG.	Dessertspoonful ev	erv	7 t	WO	. 1	hre	ee.	01	r fe	2112	· he	21170

SIG.—Dessertspoonful every two, three, or four hours.

Convalescence: The patient must be most guarded in exercise or mental occupation. Liquid diet for ten days to two weeks after normal afternoon temperature. Cardiac palpitation and excessive sweating are not infrequent, and can be controlled with a combination of quinina and belladonna. If the stools continue quite liquid with a little bright blood now and then, showing some remaining ulceration, use argentum nitras in pill form with nucis vomicæ or strychnina. The addition of extract of malt or porter to the diet is of value in a prolonged convalescence.

TYPHUS FEVER.

Synonyms. Contagious fever; ship fever; jail fever; exanthematic typhus (German); petechial typhus; spotted or putrid fever.

Definition. An acute, infectious, febrile, *epidemic* disease; highly *contagious*, and characterized by sudden invasion, profound depression of the vital powers, sickening odor, and a peculiar maculated and petechial eruption, favorable cases terminating by *crisis* about the fourteenth day. No lesion.

Cause. A special infecting germ, the character of which is unknown, but which is influenced by filth and overcrowding. Rarely seen in the United States except in seaports, where brought by emigrants.

Pathology. No constant lesion peculiar to the affection. Blood is profoundly altered, dark, thin, with lessened fibrin; tissues dark, soft, and flabby.

Symptoms. Begins abruptly; chill followed by violent fever, temperature within a few days reaching 104° to 105° F.; a frequent, bounding pulse, soon becoming small, weak, and rapid; the cardiac impulse and first sound almost effaced; severe headache, followed by violent delirium; from the fifth to the seventh day, a coarse, red, diffused, measly eruption, with a mottling of the skin all over the body, except the face, not disappearing on pressure; the face has a uniform deep, dusky flush, the skin has a glazed appearance, the pupils contracted, the eyes injected. With the development of the disease there is cutaneous hyperæsthesia, muscular soreness, and tenderness over the tibia. There is great prostration, great muscular feebleness, vertigo, tremor, and subsultus; constipation the rule. End of the second week,

the temperature suddenly declines and the patient passes into a rapid convalescence.

Complications. Pneumonia and swollen parotid glands are common.

Diagnosis. From typhoid fever, the age, season, onset of the disease, character of the eruption, and the intestinal symptoms.

Measles begin milder, with coryza and cough, and never have such pronounced nervous phenomena, but there occurs an early eruption, appearing on the face.

Cerebro-spinal fever has many symptoms in common, and but for the rarity of typhus in this country would be more puzzling. The headache and rigidity of the muscles of the neck are much more pronounced in cerebro-spinal fever and the prostration less than in typhus fever. The eruption of typhus is characteristic and should prevent error.

Prognosis. Unfavorable indications: high temperature, frequent pulse, early stupor, presentiment of death. Favorable: youth, moderate temperature and pulse, and mild nervous phenomena.

The duration about two weeks; mortality varies from five to thirty-five per cent.

Treatment. Symptomatic. As typhus fever is distinctly contagious, isolation is imperative, with immediate removal and disinfection of the patient's excreta.

All cases are benefited by small doses of the *mineral acids* alternating with *quininæ sulphas*.

For high temperature, cold sponging, cold pack, or full doses of quinina. Also, antipyrine, antifebrin, or phenacetin, or the systematic use of the cold bath or "tubbing," as now used in typhoid fever.

For the *headache* and *delirium* cold to the head. In the young and strong, a few leeches to the temple, and *chloral*, with or without the *bromides*.

For constipation, mild laxatives.

Debility: alcohol early and in full doses, or spiritus chloroformi in drachm doses whenever danger of collapse.

Convalescence: such tonics as quinina and strychnia,

CEREBRO-SPINAL FEVER.

Synonyms. Epidemic cerebro-spinal meningitis; epidemic cerebro-spinal fever; spotted fever; cerebro-spinal typhus.

Definition. A malignant *epidemic* fever, characterized by headache, vomiting, painful contractions of the muscles of the back of the neck, retraction of the head, hyperæsthesia, disorders of the special senses, delirium, stupor, coma, and frequently an eruption of petechia or purpuric spots—a subcutaneous extravasation of blood. Lesions of cerebral and spinal membranes are found at the *post-mortem*.

Cause. A special micro-organism, of oval shape, occurring mostly in pairs and faintly tremulous, resembling those found in pneumonia and erysipelas, though hardly identical. Bad hygiene seems to favor the development of this affection, but can hardly be considered its cause.

The disease seems to have a predilection for the young. Occurs most frequently in the winter months. Slightly if at all contagious.

We have no positive knowledge of the manner in which the virus gains entrance into the system.

Pathological Anatomy. The extent of lesion present in a given case depends upon the duration of the illness. In cases rapidly fatal, it is probable that the individual is overwhelmed by the poison ere the characteristic anatomical changes have had time to develop.

The changes in this disease are twofold: those due to the direct action of the infecting poison upon the blood, producing the group of symptoms constituting the fever and complications, and those giving rise to the local inflammation, viz.: Hyperamia of the membranes of the brain and spinal cord, followed by an exudation of lymph and an effusion of serum, resulting in pressure on the brain and cord. The inflammatory changes are more marked in the membranes at the base of the brain than elsewhere. The lungs, spleen, stomach, liver, kidneys, and bladder are in various stages of congestion.

If the patient survive long enough inflammatory changes occur in the cranial and special nerves and the organs of special sense.

Symptoms. Divided, according to the severity of the lesion, into three groups: the *common* form, the *fulminant*, and the *abortive*.

The Common Form begins abruptly with a chill, excruciating headache, persistent nausea, vomiting, vertigo, and an overwhelming sense of weakness. Within a few hours the muscles of the back of the neck become rigid and retracted (tonic spasm), with decided pain upon moving the head; this rigidity and retraction soon extends to the back, when opisthotonus occurs. There is great restlessness, and the surface of the body becomes highly sensitive (hyperæsthesia). Cramps in the muscles of the legs and elsewhere, and spasmodic twitchings of the lips and eyelids come and go, and, finally, convulsions or delirium occur. Intolerance of light, and in some cases amaurosis, more or less deafness, loss of sense of smell and taste soon following. The temperature and pulse records are irregular. From the first day to the fifth an eruption of petechiæ or purpura occurs in the majority of cases, and also an herpetic eruption beginning as herpes labialis appears. The tâche cerebral is usually to be obtained. The disease reaches its height in from three to eight days, and passes into stupor and coma, or ameliorates and passes into a protracted convalescence.

The Fulminant Form. Severe chill, depression, and in a few hours collapse. The patient is overcome by the poison and never reacts.

The Abortive Form consists of one or more pronounced characteristic symptoms during the course of an epidemic.

Complications. Pneumonitis; endocarditis; pericarditis; typhoid fever; pleuritis; intestinal catarrh in infants.

Sequelæ. Result from thickening of either the cerebral or spinal membranes. Persistent headache; blindness, or deafness, partial or complete; mental feebleness; chronic hydrocephalus; epilepsy, or different forms of spinal palsies.

Diagnosis. *Typhoid fever* begins slowly, has a characteristic temperature record, *without so intense* headache, muscular rigidity, opisthotonus, vomiting, early delirium, ending in coma.

Typhus fever has higher fever, is of longer duration, and has a peculiar measly eruption, is not attended with muscular rigidity and retraction, hyperæsthesia, nor disorders of the special senses.

Tubercular meningitis is not epidemic, has no characteristic eruption; is preceded by long prodromes, and runs a tedious course.

A congestive chill resembles the fulminant cases in suddenness of depression, but the latter has not the history of the former.

Inflammation of the meninges of the cord is due to exposure to cold or syphilis, and is not attended with cerebral symptoms or an eruption.

Smallpox in the first days, with the severe lumbar pains, headache, vomiting, and rash, may cause error.

Prognosis. Varies according to epidemic; from twenty to fifty, and even seventy-five per cent. die.

Treatment. There is no abortive plan of treatment for cerebrospinal fever, nor can the antiphlogistic treatment of the inflammatory symptoms be advised. Like the infectious diseases in general, sustaining measures are indicated in all but the most sthenic cases.

Nutritious and easily assimilated food, such as milk, eggs, meatjuice, and broths, should be given at regular intervals night and day. If food cannot be taken by the mouth, nutritious enemata should be substituted.

The drug that holds the highest place in the treatment of this disease is opium. The hypodermic use of morphina, gr. ½ to ½ every two or three hours; or extractum opii, gr. j every hour until stage of effusion, when quinina in tonic doses, and potassii iodidum are indicated. Prof. Da Costa alternates potassii bromidum with opium, especially in children. Ergota in the early stages would seem to be indicated, but in practice it is of little or no value.

Caution in the use of the coal-tar products must be exercised, as the relief of pain and spasm may be the onset of the stage of collapse instead of the beneficial effects of these drugs.

Locally, cold compresses to the head and spine is a most valuable measure, continued for hours at a time.

For sequelæ, potassii iodidum, a course of hydrargyrum, oleum morrhuæ, and flying blisters along the spinal column.

RELAPSING FEVER.

Synonyms. Febris recurrens; famine fever; bilious typhoid fever; spirillum fever.

Definition. An acute infectious, *contagious*, epidemic, febrile disease, self limited, characterized by a febrile paroxysm, lasting about six days, succeeded by an entire intermission of the same duration, which is in turn followed by a *relapse* similar to the first seizure. Associated with alterations in the viscera, and by the presence in the blood of a specific micro-organism—the spirillum of Obermeyer. No specific lesion.

Cause. A specific poison; contagious; acquiring the greater

activity the more filthy, crowded, and unhealthy the population amid

which it prevails.

Pathological Anatomy. During the febrile paroxysm only, the blood contains minute cork-screw-shaped organisms or spiral filaments —spirilli, constantly twisting and rotating—the spirillim Obermeteri. The spleen is enlarged and usually covered with a fresh fibrinous exudation. The capsules present a mottled appearance. The splenic pulp is more or less softened and swollen and shows enlarged Malpighian bodies. The liver and kidneys are swollen and congested.

Symptoms. No prodromes. Onset abrupt, with fever, 102°-104°; frequent, rather weak pulse, headache, nausea, vomiting, and lancinating pains in limbs and muscles, marked in the calf of the leg; second day, feeling of fullness and pressure in right and left hypochondrium, due to swollen liver and spleen; jaundice is frequent; seventh day fever ends by crisis; fourteenth day symptoms return in milder form, continuing about four days, when enters slow convalescence, much emaciated. No eruption. Several relapses may occur.

Diagnosis. Yellow fever has many points of resemblance, but has a shorter febrile stage, remission not so complete, vomiting late and characteristic, normal spleen, and the late appearance of yellow color.

Remittent fever begins with a decided chill, followed by fever and sweats, and not the progressive rise of temperature till the fifth or seventh day.

Prognosis. Recovery the rule, but protracted, and decided emaciation results.

Treatment. Expectant. Act on secretions; nourish patient and meet urgent symptoms. For fever, antipyretic doses of quinina, which, however, has no power to prevent the relapses; for pain, hypodermic injections of morphina; for nausea and vomiting, acidum carbolicum or cerii oxalas; during remission, ferrum and quinina in tonic doses.

PERIODICAL FEVERS.

These affections are characterized by the distinct periodicity of the phenomena, having intervals during which the patient is wholly or nearly free from fever.

INTERMITTENT FEVER.

Synonyms. Ague; chills and fever; malarial fever; swamp fever. Definition. A paroxysmal fever, the phenomena observing a regular succession; characterized by a cold, a hot, and a sweating stage, followed by an interval of complete intermission or apyrexia, varying in length according to the variety of the attack and the presence in the blood of the hæmatozoa of Laveran.

Cause. The presence in the blood of a specific vegetable microorganism. Klebs and Tommasi-Crudeli claim to have isolated a germ—Bacillus Malariæ—from the low-lying atmosphere over marshes and from the soil, which produced a malarial paroxysm with enlarged spleen in an inoculated rabbit.

Laveran discovered a germ in the human blood of patients suffering from malarial fevers which is now known as the hæmatozoa of Laveran, and which has since been found always present in malarial attacks. These germs are true parasites and exhibit several varieties of form and size, and it is possible that there may be several species which are capable of causing the distinct types of the disease, as tertian, quartan, intermittent, or remittent.

Laveran describes the chief forms of the hæmatozoa as consisting of amæboid spherical bodies with nuclei; crescentic shapes with nuclei; rosettes; and flagellate bodies. Laveran considers the parasite as a single but polymorphic organism, and a particular form of the germ is peculiar to a particular type of the disease. Osler, who has devoted much time to the study of the subject, "believes that different forms of the germ belong to distinct species, and that they are not all different stages in the development of one microbe."

The period of incubation varies from a few days to weeks, months, or even years, an auxiliary condition, such as exposure to cold, over-exertion, excesses in eating and drinking, or great excitement, often being necessary to give efficiency to the special cause.

Either sex and all ages are susceptible to the poison.

The mode of infection is not positively understood. It often enters the system in the inspired air, and no doubt also in contaminated drinking-water or other fluids.

Pathological Anatomy. Blood dark, from the formation of pigment (*Melanæmia*). Spleen engorged and swollen (*Ague cake*). Liver swollen and engorged during paroxysm.

Varieties. Quotidian when a daily paroxysm; tertian when every other day; quartan when it occurs first and fourth days; octan when weekly; duplicated quotidian when two paroxysms daily; duplicated tertian, two every second day; double tertian, daily paroxysm, but more severe every second day. Dumb ague, or masked ague, presents irregularity of the characteristic phenomena.

Symptoms. Each paroxysm has three stages, the cold, hot, and sweating

Cold stage begins with prodromes, lassitude, yawning, headache and nausea, followed by a chill; the teeth chatter, skin pale, nails and lips blue, the surface rough and pale, the so-called goose-skin, or cutis anserina, nausea, and great thirst, while the thermometer in the axilla or mouth shows a decided rise of temperature, 102° F.—104°; these phenomena continuing from one-half to an hour.

Hot stage begins gradually, by the shivering ceasing, the surface becoming hot and flushed, the temperature rising to 106° F., or more, pulse full, headache, nausea, intense thirst, dry, flushed, swollen skin, scanty urine, and other phenomena of pyrexia, continuing from one to eight or ten hours.

Sweating stage begins gradually, first appearing on the forehead, then spreading over the entire surface; the fever lessens, the temperature rapidly falling to 99° or 98°, pulse less full, headache lessens, and a general feeling of comfort exists, sleep often following; duration of the sweating from one to four hours, when the intermission occurs, the patient apparently well, except for a feeling of general debility.

The occurrence of the next paroxysm depends upon the variety of the attack.

The paroxysm may be ushered in by a decided pain in one or more nerves, instead of the cold stage, to wit: "brow ague."

Diagnosis. No difficulty when the characteristic *chill*, *fewer*, and *sweats* occur and enlarged spleen, and the presence of the bacillus in the blood.

Hectic fever. Distinguished by its irregularity, and occurring secondary to an organic disease; spleen usually normal size, and absence of bacillus in blood.

Pyamia produced by other causes than malaria.

Nervous chills show an absence of the temperature rise.

Prognosis. Recovery the rule. Without treatment many cases

end favorably after several paroxysms, others passing into the *chronic* form, or *malarial cachexia*.

Treatment. Cold stage can be averted and the other stages greatly modified by a hypodermic injection of either morphine sulph., gr. ½-¼, or pilocarpine hydrochloras, gr. ½, or chloroformi spts., f3j, by the stomach. Hot stage, cool drinks and cold sponging. Sweating stage, when excessive, sponging with alumen and hot water.

Intermission; at once a brisk purgative, followed by cinchona in some form, the most efficient being quininæ sulph., gr. xx-xxiv, in solution or freshly-made pills, in one or two doses, three to five hours before the expected paroxysm. Many substitutes are lauded to replace the salts of cinchona bark, but without a doubt quinina is a specific in the strictest sense of the term.

After the *paroxysms* are broken up, use *liq. potassii arsenit.*, gtt. v-x, t. d., for a long time, or *tinct. ferri chloridi*, gtt. xx, every four hours, or a combination like the following:—

R.	Ferri reducti,														
	Quininæ sulph.,														
	Acidi arseniosi,														
Ft	Ol. pip. nigr., .	٠	٠	٠	٠	٠	٠	٠	٠	٠	٠	٠	۰	gtt. xv.	M.

Sig.—One pill after meals, continued for one month or longer.

Relapses being common, quinina should be given on the second or third day, fourth to the sixth, twelfth to the fourteenth, and nineteenth to the twenty-first days.

If the *spleen* be *enlarged*, and it usually is in long-continued cases, or those becoming chronic (marked anæmia, gastric distress, constipation with depression of spirits associated with headache coming in paroxysms are the prominent symptoms of the cachexia), use locally *ung. hydrargyri iodidi rubri* and internally *ergota*, or *ergotine* (aq. ext.) hypodermically over the splenic region, and tonic doses of *quinina*, *ferrum*, and *arsenicum*.

REMITTENT FEVER.

Synonyms. Bilious fever; bilious remittent fever; marsh fever; typho-malarial fever.

Definition. A paroxysmal fever, with exacerbations and remissions, but in which the temperature is constantly above the normal;

characterized by a moderate cold stage (which does not recur with each paroxysm); an intense hot stage, with violent headache and gastric irritability; and an almost imperceptible sweating stage, which is frequently wanting.

Cause. The presence in the blood of a specific vegetable microorganism, either the *Bacillus malariæ* (Klebs and Tommasi Crudeli),

or the hæmatozoa of Laveran (vide Intermittent Fever).

Pathological Anatomy. Blood dark (*Melanæmia*); spleen enlarged, soft, filled with blood, and of an *olive* color; liver congested and swollen, and of a *bronze* hue; the brain hyperæmic and olive-colored; gastro-intestinal canal markedly hyperæmic.

Symptoms. Cold stage: moderate chill, the temperature rising one or two degrees, coated, dry tongue, oppression at the epigastrium,

slight headache, and pains throughout the body.

Hot stage: persistent vomiting, furred tongue, full pulse, rising to 100 or 120, flushed face, injected eye, violent headache, pains in limbs and loins, hurried respiration, the temperature rising to 104° F., or 106°. The bowels costive, stools tarry and offensive, the urine scanty, high colored and ureaic, and the surface becoming yellowish. Delirium occurs when the temperature is very high.

Sweating stage: after six to twenty-four hours, the above symptoms abate, and slight sweating occurs, the pulse, headache, and vomiting subside, and the temperature falls to 100° F., or 99° F.

This is the remission, during which the symptoms of a mild pyrexia

are present.

After some two to eight or twelve hours, the symptoms of the hot stage return, generally minus the chill, and this is termed the exacerbation, which is in turn again followed by the remission.

Duration. From seven to fourteen days the average. Frequently the fever ceases to remit, and instead becomes continuous, the symptoms resembling, if they are not identical with, the typhoid state, whence the term typho-malarial fever, or malario-typhoid fever.

Sequelæ. The *malarial cachexia* results when the poison has not been eliminated from the system.

Persistent headache and vertigo are the results of the intense meningeal hyperæmia that sometimes occurs.

Diagnosis. In intermittent fever each paroxysm begins with a chill, while the chill seldom recurs in remittent fever; a distinct intermission follows each paroxysm of the intermittent form, while a

remission occurs in remittent, the thermometer showing that the fever does not wholly disappear; during the *intermission* the patient is apparently well; such is not the case in the remission of remittent fever.

Typhoid fever is mistaken for remittent fever, but the absence of the characteristic temperature record, diarrhea, eruption, tympanites, deafness, and severe prostration should prevent such an error.

A diagnosis can always be made absolutely by an examination of the blood

Prognosis. Uncomplicated cases are favorable.

Treatment. Quininæ sulphas, gr. xvj-xx per diem, is the remedy. Better administered during the remission, if possible. If an irritable stomach prevents its administration by the mouth, use it by the hypodermic method or in a suppository. During the hot stage, cool sponging, cold to the head, and if a tendency to cerebral congestion, dry or wet cups to the nape of the neck and—

The same precautions are essential after the paroxysms are broken up, to prevent their return on the septenary periods, that were recommended for intermittent fever.

For convalescence: Ferrum, arsenicum, and strychnina are indicated.

PERNICIOUS FEVER.

Synonyms. Congestive fever; malignant intermittent fever; malignant remittent fever.

Definition. A malignant, destructive malarial fever, which may be of the intermittent or remittent form; characterized by *intense congestion* of one or more internal organs, *together* with dangerous perversion of the functions of innervation.

Cause. A high degree of malarial poison. (Vide Intermittent Fever.)

Varieties. Gastro-enteric; thoracic; cerebral; hemorrhagic; algid,

Symptoms. Any of these varieties may begin either as an *intermittent* or *remittent* fever; again, the *first paroxysm* is rarely pernicious, but appears as the ordinary malarial attack.

The gastro-enteric variety has as distinctive features, intense nausea and vomiting, purging of thin discharges mixed with blood, tenesmus, burning heat in stomach, intense thirst, frequent, weak pulse, face, hands, and feet cold, with shrunken features, and an intense depression of all the vital forces. This condition continues from half an hour to several hours, when either an inter- or a remission occurs.

Thoracic variety often combined with the one just described. Its characteristic features are due to overwhelming congestion of the lungs, such as violent dyspnæa, gasping for air, fifty to sixty respirations per minute, oppressed cough with slight amount of blood-streaked sputa, frequent, weak pulse, cold surface, and terror-stricken features. Duration same as the above.

Cerebral variety, due to intense congestion of the brain; sometimes effusion of serum into the ventricles, or even rupture of small bloodvessels. Characterized by violent delirium, followed by stupor and coma, slow, full pulse, the surface either flushed or livid. Cases may either resemble apoplexy—comatose variety, or acute meningitis—delirious variety. Duration same as the other forms.

Hemorrhagic variety, or the yellow disease, as it has been termed, begins as an ordinary inter- or remittent fever, soon followed by signs of internal congestion, to wit: nausea, vomiting, dyspnæa, severe pains over liver and kidney, continuing for a few hours, when the surface suddenly turns yellow and bloody urine is voided, after which an inter- or remission and marked abatement occur, to be sooner or later followed by a second paroxysm, which is more severe, with signs of cerebral congestion. Blood may also escape from other parts than the kidneys.

Algid variety is characterized by intense coldness of the surface, while the rectal temperature ranges from 104° to 107° F. The attack begins with a chill, which is soon followed by fever of variable duration, when the body becomes cold, the axillary temperature falling to 90°, 88°, or even 85° F., a cold sweat covers the surface, the tongue is

white, moist, and cold, the breath is icy, the voice feeble and indistinct, the pulse slow, feeble, and often absent at the wrist, and with all these symptoms, the patient complains of a sensation of burning and intense thirst. The mind is clear, but the countenance is death-like.

Duration. Pernicious fever, in any of its forms, may continue from a few hours until one, two, or three days. Recovery is rare after a *second*, almost never after a *third*, paroxysm.

Diagnosis. A positive diagnosis can always be made by an examination of the blood.

Yellow fever is most apt to be confounded with the hemorrhagic variety, and as they both occur in the same localities, the diagnosis is difficult; the early yellowness of the surface, with hæmaturia, and the absence of the black vomit, and epidemic prevalence, are the chief points of distinction.

The cerebral variety may be mistaken for cerebral apoplexy, meningitis, and uramic convulsions. Nor is it always an easy matter to differentiate between these conditions.

The gastro-enteric variety may be mistaken for the early stage and the algid variety for the later stage of cholera, but the epidemic prevalence of the latter should be of material aid in determining the diagnosis.

Prognosis. In all varieties the result is unfavorable, unless it can be controlled prior to the *second* paroxysm. Cases in which an *intermission* occurs are better controlled than where a remission follows. The mortality is *one* in *eight* from all plans of treatment.

Treatment. The first indication in all varieties is to bring about reaction. In the cold stage, heat to the surface, with stimulating lotions; in the hot stage, cold to the surface and the hypodermic injection of morphina, gr. ¼, at once. After reaction, quininæ sulphas, not less than gr. xl, repeated p. r. n.; administer by stomach, rectum, or, better still, by hypodermic injection. Dr. Bartholow pronounces the following one of the best formulæ for the hypodermic use of quinina:—

Quininæ disulph.,								
Acid. sulph. dil.,						٠	mc	
Aquæ font.,								2.6
Acid. carbol. liq.,							mv.	M.

The new salt, quinina bimuriatica carbanidata, is highly recommended, being very soluble, for hypodermic use.

The following formula, known as "Warburg's Tincture," has during the last few years gained considerable reputation in the various forms of malarial fevers:—

Ŗ.	Rad. rhei, P. aloe soc. and Rad. angelica officinalis,
	Rad. helenii, Crocus Hispan., Sem. fœniculi, and Cretæ preparat., āā ¾ ij
	Rad. gentian, Rad. zedoar, P. cubeb, G. myrrh, G. camphor, and Boletus Lari-
	cis āā žj
	Confect. damocratis,*
	Quininæ sulph., 3 lxxxij
	Spts. vini rect., O xx
	Aquæ puræ,

Macerate in a water bath twelve hours, express, and filter.

M.

Each half ounce contains quininæ sulphas, gr. vijss. If the stomach is too irritable to retain the tincture, the tincture may be evaporated to dryness and administered in *capsules*, each containing the equivalent of either one or two drachms.

For the gastro-enteric variety, Prof. Da Costa suggests-

M.

In pills every half hour until the character of the stool is changed.

*Formula of Confectio damocratis:—	
Cinnamon, xiv gm. Myrrh, xj gm.	
White agaric, Spikenard, Ginger, Spanish saffron, Treacle, Mustard seed, Frankincense, and Chian	
Turpentine,	
of harwort, Juice of rape cistus, Strained storax, Opponex, Strained galbanum, Balsam of Gilead,	
Oil of nutmeg, Russian castor, āā viij gm. Water germunder, Balsam tree fruit, Cubeb, White	
pepper, Seeds of carrot of Crete, Poley mont, Strained bdellium, vij gm.	
Gentian root, Celtic hard, Leaves of Dittany of Crete, Red rose, Seeds of Macedonium, Parsley,	
Sweet-fennel seeds, Seeds of lesser cardamon, Gum arabic, Opium, v gm. Sweet flag, Wild valerian, Anise seed, Sagaper-	
num, iij gm. Spigrul, St. John's wort, Juice of açacia, Catechu,	
Dried bellies of skunk, äā ijss gm. Clarified honey, cmxv gm	١.
The roots to be finely powdered and the whole mixed thoroughly.	

M.

For the thoracic variety, dry or wet cups and ammonii carbonas, caffeinæ citrat., and hypodermic injections strychninæ sulphas.

For the *cerebral* variety, venesection, or cups or leeches to the neck, cold to the head, prompt purgation, and action on the kidneys and skin

For the algid variety warmth to the surface, hypodermic use of morphina and atropina, and the free use of ammonii carbonas and alcoholic stimulants.

For the hemorrhagic variety, purgatives, morphina hypodermically, and either acidum sulphurici dil., acidum gallic, Monsel's solution, or terebinthina, for the hemorrhages.

The following is highly spoken of for hemorrhages:-

R .	Ext. ergotæ fld., .						. 3 ss
	Acid. sulph. dil.,			٠		4	. f z jss
	Acid. gallic,						· 31
	Syr. zingib.,						
	Aquæ, q. s.,						
Sic	Dessertsmoonful						

After the paroxysms are controlled, a long course of ferrum and arsenicum, with quinina on the septenary days.

YELLOW FEVER.

Synonyms. Yellow Jack; bilious malignant fever; typhus icterode: Mediterranean fever; sailors' fever; black vomit.

Definition. An acute, infectious, paroxysmal disease, of *three stages*, the *febrile*, the *remission*, and the *collapse*; characterized by violent fever, yellowness of the surface, and "black or coffee-ground vomit." Tendency fatal; one attack confers immunity from a second. Not contagious.

Cause. A specific poison, existing only with a high temperature and destroyed by frost. *Not due to the malarial poison*. Usually seen during the months of June, July, August, and September.

The true home of yellow fever is in the tropics.

Guiteras mentions three areas of infection: 1. The focal zone in which the disease is never absent, including Havana, Vera Cruz, Rio, and other Spanish-American ports. 2. Peri-focal zone or regions of periodic epidemics, including the ports of the tropical Atlantic in

America and Africa. 3. The zone of accidental epidemics, between the parallels of 45° north and 35° south latitude.

Epidemics are due to the introduction of the specific germ, either from patients affected with the disease or through infected articles.

Neither age, sex, race, nor social condition has immunity. One attack protects the individual.

Pathological Anatomy. Skin lemon or greenish-yellow color, due to dissolution of the red blood corpuscles; heart softened by granular degeneration; stomach, veins deeply engorged, the mucous membrane softened, and containing more or less "coffee-ground" matter, which consists of blood corpuscles deprived of their hæmoglobin, white corpuscles, epithelial cells, and debris. Intestines much the same as the stomach; liver, yellow color and a fatty degeneration of the hepatic cells; kidneys, granular degeneration of the epithelium of the tubules. The spleen presents a singular lack of pathological change.

Symptoms. The *incubation* lasts from twenty-four hours to six and exceptionally ten days. The more severe the epidemic the shorter the period of incubation.

First stage, the febrile, beginning either with the prodromata of malaise, headache and anorexia, or suddenly with a chill, high fever, in a few hours reaching 104° to 106° F., rapid pulse, 90-100 beats, brilliant eye, flushed countenance, coated tongue, irritability of the stomach, and severe neuralgic pains in the head, limbs, epigastrium, back, and large joints. The patients are restless and anxious, with a feeling of general prostration. In severe attacks delirium is frequent. The urine is scanty, acid, high colored, and contains albumin. A peculiar and characteristic odor is emitted from the patient. Duration of the first stage from thirty-six hours to three or four days.

Second stage, the remission, when the temperature declines to 100° or 99° F., and all the distressing symptoms abate or subside, and with some critical evacuation, convalescence occurs, or, more commonly, after from a few hours to one to four days, the—

Third stage, the stage of collapse, or the period of secondary fever, is ushered in by a return of all the symptoms of the first stage in an exaggerated form, followed by yellowness of the skin, passing to a deep mahogany color, black vomit, and hemorrhages from other parts, feeble pulse, cold surface, irregular respiration, and death from exhaustion, the mind remaining clear until the end.

The above symptoms represent a *sthenic* case; other varieties are the *algid*, *hemorrhagic*, and *typhus*.

Duration. Depends upon the variety; from a few hours to a few days. Rarely continues longer than one week.

Diagnosis. Pernicious fever, hemorrhagic variety, is apt to be mistaken for yellow fever. Yellow fever is a disease of one paroxysm, and one remission, epidemic, with albuminuria and black vomit. Pernicious fever has more than one paroxysm, not epidemic, rarely black vomit or albumin in urine. A valuable diagnostic point from malarial fevers is that quinine has no similar influence over yellow fever.

Prognosis. One in four perish. Short cases unfavorable, as are the hemorrhagic and algid varieties.

Treatment. No specific: a "self-limited" disease. The indications are to keep the patient quiet in bed, and treat the symptoms as they arise, and to nourish the patient. Good nursing, ventilation, early emesis and purgation, with diaphoretics and diuretics, are apparently beneficial. Large doses of quinina, early in the attack, for high temperature, by hypodermic method. For the irritable stomach, ice slowly dissolved in the mouth and acidum carbolicum, gr. ¼ in aqua menthæ pip., every two hours, alternated with liquor calcis and milk, each an ounce, or—

R. Hydrargyri chlor, mite, gr. $\frac{1}{12}$ Morphinæ sulph., gr. $\frac{1}{2}$.

Every two hours until nausea controlled.

Every two nours until nausea controlled.

For the black vomit and hemorrhages, either liquor ferri subsulphatis or plumbi acetas. The pains, restlessness, or delirium are best controlled by the hypodermic use of morphina or atropina. Free stimulation from the onset is essential.

When an epidemic of yellow fever breaks out all persons, whose duty does not keep them with the sick, should leave the infected district at once. "The cardinal principles involved in prophylaxis during an epidemic are summed up in the oft-quoted words, 'Isolation, disinfection, and depopulation.'"

ERUPTIVE FEVERS.

As a group, the eruptive or exanthematous fevers have many features in common. All have a period of incubation, are characterized

by a fever of more or less intensity preceding the eruption, by an eruption which is peculiar to each, occurring most commonly in childhood, rarely attacking the same person twice, very prone to occasion serious sequelæ, and are contagious. Their origin is as yet undetermined.

SCARLET FEVER.

Synonym. Scarlatina, from the (old) Italian scarlattina, scarlatto (red).

Definition. An acute, self-limited, contagious, *infectious* disease, usually of childhood; characterized by high temperature, rapid pulse, a diffused scarlet eruption, terminating with desquamation, inflammation of the mouth and throat, and frequently more or less grave nervous phenomena. Serious sequelæ frequently follow an attack. One attack confers immunity from the disease.

Pathological Anatomy. An acute inflammation of the skin, with exudation—a true *Dermatitis*. A *granular* change in all the glandular structures, most marked in the Peyerian glands, although also occurring in the stomach and kidneys. Streptococci are usually found in abundance in the glands and areas of suppuration.

Cause. A specific poison, maintaining its vitality for a long time. Highly contagious, the contagion residing chiefly in the desquamated epidermis. Klebs' micrococci, the "monas scarlatinosum," may prove to be the poison. *Incubation* short, one to seven days.

Varieties. Scarlatina simplex, scarlatina anginosa, and scarlatina maligna.

Symptoms. A mild case is a very trivial affection, but in its severest form there are few diseases more malignant.

Onset sudden with a decided *chill* and *vomiting* (in infants, convulsions), pain in throat followed by *high fever*, soon reaching 105°; a *rapid pulse*, 110 to 140, being frequent. At the end of twenty-four hours a *bright scarlet rash* appears on the neck and chest, spreading over the entire body within a few hours; the eruption is not raised, there is no intervening healthy skin, and scattered irregularly are points of a darker hue. With the appearance of the eruption occurs burning heat of surface, pain in the throat, and difficulty in deglutition, the throat on inspection presenting the appearance of a catarrhal inflammation. Tongue at first furred, later red, with prominent

papillæ—the "strawberry tongue." There also occurs headache, great restlessness, and in severe cases delirium. Diarrhæa quite common.

On the fourth or fifth day the fever declines by *lysis*, the eruption fading, and on the sixth or eighth day *desquamation* begins, continuing for ten days, two weeks, or longer, the *convalescence* being slow, the patient *emaciated* and *pale*.

Scarlatina anginosa are cases like the above with the addition of great inflammation and swelling of the pharynx, nose, palate, tonsils, and neighboring glands, the swollen glands pressing upon the surrounding parts, causing difficulty of breathing and of deglutition.

Scarlatina maligna are cases with decided nervous phenomena, to wit: convulsions, delirium and muscular twitching, the temperature reaching 107° to 110°, the pulse rapid, feeble, and irregular, the eruption delayed, of a purplish color, and in patches.

Complications. Three conditions are always to be looked for in all cases of scarlet fever; otilis, affections of the joints and acute nephritis, each adding to the gravity of the attack.

The association of *diphtheria* with scarlet fever adds to the severity of the attack. The engrafting of these two diseases on the same individual is not an infrequent occurrence.

Sequelæ. Chronic sore throat; conjunctivitis; otorrhæa; chronic diarrhæa; subacute rheumatism; chorea; endocarditis; pericarditis; pleuritis; acute Bright's disease, and cutaneous dropsy.

Diagnosis. A typical case should cause no difficulty; the high fever, rapid pulse, sore throat, and early scarlet eruption, followed by desquamation, should leave no doubt.

Measles: the above symptoms are absent, and *catarrhal* symptoms present, the later appearance of the eruption and the difference in its character.

Smallpox: eruption on the third day in spots, changing to pustules with secondary fever.

Dengue or break-bone fever: absence of the above typical symptoms, and presence of severe pains in the bones.

Diphtheria: gradual invasion, great prostration, and no eruption, but the frequent complication of scarlatina and diphtheria must be remembered.

Meningitis may be suspected from the symptoms of *scarlatina* maligna: the epidemic influence, eruption, and rapid pulse are points of difference.

Prognosis. Depends upon the character of the attack and the association of complications. Acute nephritis, endo- and pericarditis, and pleuritis add to the gravity. The prognosis is more grave, however, from the association of diphtheria, the inflamed naso-pharynx presenting fertile soil for the ravages of that grave malady. Never can be positive of the result. Mortality ranges from ten to twenty-five per cent.

Treatment. As with other eruptive fevers, so with scarlatina, there are no specific remedies by means of which it can be arrested or controlled. Symptomatic treatment judiciously applied, however, may afford relief and diminish the fatality.

The indications are for rest in bed, good ventilation, isolation, disinfection, cooling drinks, action upon the skin, and light nourishment.

For a case of scarlatina simplex small doses of hydrargyri chloridi mite, sodii bicarbonatis, and pulvis ipecac every two or three hours until thorough movement of the bowels occur, will favorably influence the fever and rapid pulse in mild cases.

For cases with high fever and rapidity of pulse, aconitum, digitalis, quinina, or antifebrin, gr. j-ij, every couple of hours, or acetanilidum, gr. j-ij-iv, every two or three hours, with cool sponging, cold bath, douche, or pack.

If the surface be pale, the circulation feeble, and the eruption tardy in appearing, benefit will follow the administration of *tinctura digitalis* or *tinctura belladonnæ*, gtt. j-x, according to age.

With the appearance of the *eruption* anoint the entire body, save the head, with *vaseline* night and morning. *Acidum carbolicum*, gr. v, may be added to the ounce of vaseline. The inunction of vaseline or other fat acts beneficially in many ways. It reduces the fever by its soothing the cutaneous burning and irritation, later on when desquamation occurs it limits the source of further infection by preventing the diffusion of the otherwise dry scales in the air, and finally it protects the surface from the influences of sudden changes of temperature, thus to a great extent avoiding the danger of nephritis.

For scarlatina anginosa, internal use of-

R.	Tinctura ferri	chlor.,						٠		fʒij
	Glycerinæ, . Aquæ,									fŽj
	Aquæ,				٠	q.	s.	ad	٠,	f Ѯ ij.

Sig.—One half to one teaspoonful every two hours, undiluted, according to age.

Externally, ice or cold compresses, unless they cause chilliness, if so, heat. Astringent gargles and small pellets of ice dissolved in the mouth are of use. The throat and nasal cavities are kept clean and the breathing relieved by the use of Dobell's solution used with a hand atomizer every hour. The formula is:—

Ŗ.	Acid. carbolici, Sodii biboracis.	٠	٠	٠	٠	٠	٠	٠	٠			3 iss
	Sodii bicarb., . Glycerini, .										āā	3 ij
	Aquæ,								. g	.s.	ad.	Öij. M.

The use of this solution proves grateful to the patient, relieving the breathing through the nose by loosening the tenacious secretions. An excellent gargle for those old enough to properly use one is:—

R.	Thymol,										٠				gr. iv	
	Glycerini,			٠							٠	٠			fĪj	
	Aq. dest.,							٠			٠	٠	٠		f℥j.	
SIG.	—A throat	W	ash	ı.	If	ne	ces	sai	У	di	lut	e	fui	th	er.	M.

For scarlatina maligna, in addition to ferrum and quinina, the chief reliance must be on alcoholic stimulants, guiding the amount by their effects. In children, wine-whey, milk-punch, and egg-nog are eligible for the administration of stimulants and nourishment.

Convulsions, or only great restlessness and muscular twitchings, are the result of the high grade of fever, and call for prompt treatment. My experience in such cases is against the group of antipyretic drugs, as not meeting the indication promptly enough. The cold wet pack or the cold bath with cold affusion or the ice cap are the most efficient and rapid means of reducing the temperature and relieving the nervous disturbances.

Prof. Da Costa advocates the administration of *ammonii carbonas*, in small doses at frequent intervals, to prevent the liability of heart-clot, and for its salutary influence over the disease.

It is claimed that a characteristic micrococci is found in the blood, and that, consequently, the disease can be favorably influenced by acidum carbolicum, thymol, or acidum boricum; an eligible way of administering acidum carbolicum is the syr. ammoniæ phenatis (Déclat), f3ss-f3j, four to six times daily.

There can be no doubt but that the complications and sequelæ attending scarlet fever constitute the principal dangers of the disease. If diphtheria develop, the combination of ferrum and hydrargyri chloridum corrosivum with free alcoholic stimulation are the indications

Acute nephritis is so commonly associated with, or follows the decline of, scarlatina that it is a prudent practice to examine the urine daily. If albumin appear add to the ferrum, tinctura cantharidis in minute doses, and dropsy and uræmic symptoms may be prevented. If, however, true scarlatinal nephritis does develop the following mixture of Hughes-Bennett, with saline purgatives and either a hot bath or the hot-air bath twice or oftener daily, will be followed with improvement:—

₿.	Potassii acetat., .											
	Spts. æther nitrosi,										f 3 ss	2.5
	Aquæ,	٠		٠	۰	۰	٠	q.	S.	ad.,	tžij.	Μ.

Or-

R. Hydrargyri chlor. mite,
Pulv. scillæ,
Pulv. digital., gr. ¼-½-j.
M. et ft. pil., No. j.

Sig.—One such pill every three or four hours.

If uræmic convulsions occur use the hot-air bath, cupping over the kidneys, hypodermic injections of *pilocarpus*, the inhalation of *chloroformum*, or maybe the rectal use of *chloral hydrate* with or without *potassii bromidum*. Uræmic symptoms are often remarkably controlled by full doses of *sodii benzoas*.

For scarlatinal rheumatism the use of ferrum alternately with the following:—

R.	Ammonii salicyl.,					۰						∂iv-ʒij	
	Elix. simplicis, .	٠					٠					f 3 ss	
	Syr. simplicis,												
	Tinct. card. co., .	۰		۰	٠	٠		٠	٠	۰	٠	f 3 ss.	Μ.
C1	CC C 1 111	. 1	1 0					- 2	1.2				

Sig.—Teaspoonful diluted four times daily.

For inflammation of the middle car it is much better to puncture the drum membrane than to allow its ulceration; insufflations of acidum boricum and the internal use of ammonii chloridum.

For the various other sequelæ, the treatment is the same as if they occurred primarily, plus tonics.

The disease being infectious, every means should be taken to pre-

vent its spread, to wit: isolation, cleanliness, disinfection, and fumigation.

Small doses of *quinina*, in those exposed, is said to prevent or modify the severity of an attack, but no true prophylactic is known.

MEASLES.

Synonyms. Morbilli; rubeola.

Definition. An acute *epidemic* and *contagious* disease; characterized by catarrhal symptoms, referable to the naso-broncho-pulmonary mucous membrane, fever, and a crimson eruption which terminates by desquamation.

Cause. A specific poison, with a special susceptibility for child-hood. Contagious by contact, and can be communicated by inoculation. One attack, as a rule, protects from a second. *Incubation*, ten days.

Pathological Anatomy. There are no special anatomical characters exclusive of the eruption, which is considered among the symptoms of the disease.

Symptoms. Onset gradual following a chill or with irregular chills, fever, the temperature rising to 101° or 102°, muscular soreness, headache, and intense nasal, pharyngeal, and laryngeal catarrh. The eyes are reddened and tears flow over upon the face. On the evening of the second day a decided remission takes place in the fever, the catarrh continuing; on the fourth day occurs an eruption of a crimson color on the face, soon spreading over the body, in the form of dots, slightly elevated, which coalesce into irregular circles or crescents, and with the appearance of the eruption the fever returns, the catarrh is aggravated, but the character of the discharge, instead of remaining clear and watery, becomes turbid, thick, and yellowish, and extends to the bronchial mucous membrane. About the ninth day (the fourth of the eruption), the eruption fades, the symptoms abate, and slight desquamation occurs. Some cough and catarrh may remain for a long period.

Black measles, sometimes called hemorrhagic rubeola, or camp measles, is a variety occurring in camps and jails, in which occur dangerous chest symptoms, and black spots or petechiæ from deteriorated blood, and severe prostration.

Rather common complications are tonsillitis, and lobar or catarrhau pneumonia.

Sequelæ. In those of *strumous diathesis*, scrofula or tuberculosis may develop.

Diagnosis. A typical case begins gradually, with chilliness, nasal catarrh, watery eye, and fever, which decline before the eruption, rising afterward, the eruption crescentic in shape and of a crimson color, followed by desquamation.

Scarlet fever: absence of catarrh, and earlier appearance and different character of the eruption, with high fever and rapid pulse.

Prognosis. As a rule, a perfect recovery. If tuberculosis develop, the prognosis is bad. Black measles, the majority succumb.

Treatment. *No specific.* Mild cases require no medicine, simply regulating the diet and bowels, and cool sponging; the indications are to render the patient as comfortable as possible, the disease pursuing a favorable course without therapeutical interference.

If the febrile reaction is high the following soon controls it:-

R.	Tinct. aconiti rad., .						
	Spts. ætheris nitrosi, .						
	Liquor. potassii citrat.,	٠		٠	ad	fgj.	M.
Ever	v two hours						

For the *pruritus* of the *eruption*, the local use of *oils* and *fats*. For *catarrhal symptoms*, inunction of the nose, neck, and chest with *camphorated oil* and small doses of *pulv. ipecac et opii* at bedtime; if the catarrh extends to the bronchial mucous membrane, *expectorants*.

During convalescence, for the strumous, protect from exposure, and administer *oleum morrhuæ* with *syr. ferri iodidi*. For *black measles*, bold stimulation, and *ferrum* and *quinina*.

RÖTHELN.

Synonyms. Rubella; epidemic roseola; German measles; French measles; false measles.

Definition. An acute, self-limited disease; characterized by mild fever, suffused eyes, cough and sore throat, enlargement of the lymphatic glands of the neck, and a rose-colored eruption, in patches of irregular size and shape, appearing on the first day.

Cause. Propagated by infection. That a peculiar germ exists is probable, but thus far it has not been isolated. *Incubation* from one to three weeks.

Symptoms. Onset sudden, with mild fever, suffused eyes, with little or no coryza, sore throat, and enlargement of the cervical glands, not limited to those about the angle of the jaw, as in scarlatina. Any time from the first to the fourth day appear rose-colored spots, size of a pin-head, slightly elevated, which coalescing, form irregular shaped and sized patches, with intervening healthy skin, fading on the upper part of the body while just appearing on the lower. Symptoms all terminate within a week by lysis, the patient showing no ill effects from the attack.

Diagnosis. From *scarlet fever*, by absence of high fever, the rapid pulse, the color and character of the eruption, and the sequelæ.

From *measles*, by absence of intense catarrhal symptoms, the late appearance of eruption, and its crescentic shape.

Prognosis. Most favorable.

Treatment. Mild laxatives and restricted diet. If *fever* high, saline mixture. For *itching* of skin, sponging with vinegar and water, or inunction with *vaseline*.

SMALLPOX.

Synonym. Variola.

Definition. An acute epidemic and *contagious* disease; characterized by severe lumbar pains, vomiting, and an initial fever, lasting from three to four days, followed by an eruption, at first *papular*, then *vesicular*, and afterward *pustular*; the development of the pustule being accompanied by a *secondary fever*, during the presence of which grave complications are prone to occur.

Causes. A specific poison whose nature is unknown, maintaining its contagious vitality for a long period. "There is no contagion so strong and sure as that of smallpox, and none that operates at so great a distance." (Watson.) There is no period, from the initial fever to the final desquamation, when the disease is not contagious, although the stage of suppuration is the most virulent. One attack, as a rule, protects from a second. Vaccination has a positive protective influence from the disease, an extensive observation having fully proven that in proportion to the efficiency of vaccination is

the rarity and mildness of variola. *Incubation*, fourteen to sixteen days.

Pathological Anatomy. A granular and fatty degeneration occurs in the liver, spleen, kidneys, and heart. The *pustules* are found in the larynx, trachea, bronchial tubes, and on the pleura.

Varieties. Discrete; confluent; malignant; varioloid or modified smallpox.

Symptoms. Discrete form. Onset sudden, with a violent chill, vomiting, and agonizing pains in the back, shooting down the limbs; fever, in short time rising to 103° or 104° F.; full, strong, and rapid pulse, ranging from 100 to 130; the face red, eyes injected, intense headache and sleeplessness; prostration great from the very onset. Delirium and convulsions occur at times. During the third day the characteristic eruption makes its appearance, first on the forehead and lips, consisting of coarse red spots. With the appearance of the eruption all the marked symptoms of the fever abate, the patient feeling quite comfortable. On the fifth day of the disease the spots become papules; on the sixth day, transformed into vesicles, which are soon umbilicated; on the eighth day the vesicles change to pustules; on the ninth day the pustules are entirely purulent, and each surrounded with a broad red band—the halo or areola, the face becoming swollen, and the features distorted; on the eleventh day, pus oozes from the pustules, and drying, forms the scab, or crust, which, on the seventeenth to twenty-first day drops off, leaving a red, glistening depression or pit, soon changing into a white cicatrix. With the formation of the pustules (eighth day) severe rigors and fever set in, and a characteristic odor is emitted, all the original symptoms returning. This secondary fever, the fever of suppuration, is the most critical period of the disease, and is generally attended with violent delirium. In favorable cases the secondary fever subsides after three or four days, and convalescence is established.

Confluent smallpox differs from the discrete in the greater severity of all the symptoms and the marked prostration of the patient, the eruption appearing during the second day, the pustules coalescing into large patches, causing great distortion of the features.

Malignant smallpox is characterized by the greater intensity and the irregularity of the symptoms, death resulting before the characteristic eruption appears, by convulsions or coma. In these cases hemorrhages are frequent and petechiæ are observed.

Varioloid, or modified smallpox, is the form modified by previous vaccination, or by a former attack of smallpox. Its course is shorter and milder than the other forms, the eruption appearing a day later, and is not attended with secondary fever.

During some epidemics two other eruptions are observed, appearing on the second day, one *petechial* in the form of a fine macular or spotted eruption on the abdomen and legs, "Simon's triangle"; the other an erythematous eruption on the sides and inner surface of the legs. Both disappear within forty-eight hours.

Complications. During the course of the secondary fever there is a great tendency to grave inflammations, such as pleuritis, pneumonitis, and dysentery. During convalescence, boils and abscesses on the skin are frequent.

Diagnosis. Cannot be confounded with any other disease if it has typical symptoms, such as chill, vomiting, pains in back and legs, high fever and pulse, all declining on *third day*, when the eruption appears, first spots, then papules, then vesicles, finally pustules, drying and forming crusts, and with the marked secondary fever.

Prognosis. Depends upon the variety of the attack, the age of the patient, and whether vaccinated or not. Discrete, mortality four per cent.; confluent, fifty per cent.; malignant, all perish. Under five years and over forty years of age, fifty per cent. die.

Treatment. If the patient is seen early vaccination should be performed at once; it may modify the attack. In the absence of a specific, the treatment is entirely symptomatic. Rest in bed, good ventilation, the temperature kept at 65° F., avoiding draughts. For the initial fever, full pulse and pains, phenacetin, gr. x, or antifebrin, gr. v, or acetanilidum, gr. v-x or what is better still, as more soluble, antipyrine gr. x, repeated p. r. n., are of great service, rendering the symptoms more endurable. Depressing doses must be avoided.

For the *headache*, ice bags to the head and a mustard sinapism to the nape of the neck.

For sleeplessness and restlessness or early delirium, full doses of potassii bromidum, or chloral.

For secondary fever the best remedy is quinina, gr. v, every three hours, and for cerebral excitement of this period, either full doses of potassii bromidum, by stomach, or the following by rectum:—

R .	Chloral	l,										٠			. gr. xv-xx	
	Mucil.	a	cac	cia,		٠	٠	٠	٠		٠	٠	٠	٠	· (3 ij	3.7
	Aquæ,		٠		٠					•		٠	٠	-	. fǎij.	М.
n. r.	n.															

The secondary fever being pyæmic in character, the depression should be anticipated by large doses of tinctura ferri chloridi and judicious stimulation, brandy in tablespoonful doses being most efficient.

From the onset, milk, eggs, animal broth, oysters, and beef juice should be administered every three hours. Ice is always grateful and should be given freely, and if pustules appear in the mouth, ice should be held in the mouth as long as possible, and washes of potassii chloras or acidum carbolicum employed.

The disease being contagious, isolation, ventilation, cleanliness, and disinfection are imperative.

To prevent pitting, keep patient in a dark room, well ventilated. Masks of some unctuous material, thoroughly applied, to exclude the air, have a beneficial effect. Success is claimed by a number of observers from the use of collodium applied once or twice daily. Cold water dressings constantly to face and hands are beneficial, besides allaying heat, pain, and swelling. Hot water can be used if more grateful. The water dressings should be made antiseptic with sublimate solutions, I: 5000 or I: 10,000; Ichthyol, five or ten per cent. solution, painted over the pustules several times a day, is recommended to hasten the drying up, check extensive suppuration, and prevent pitting.

VACCINATION.

Definition. Inoculation with the matter of *vaccinia* or cow-pox—bovine virus. The person properly vaccinated is, as a rule, protected from an attack of smallpox, and especially from a severe or fatal attack.

Vaccination should be performed at least twice in every individual, during infancy and at puberty; and it is safer to have it again performed if special exposure be liable or has occurred.

In practicing vaccination the skin should be rapidly scraped until the true skin is reached and is ready to bleed, the lymph being then brushed over the abraded surface; or, instead, making three or four

horizontal and transverse cuts, about four lines long, and rub the virus over them; a little blood, but not much bleeding, should result.

Symptoms. If the vaccination "takes," on the third day a papule appears; on the sixth day a vesicle has formed, with a central depression; on the eighth day a pustule, fully formed and distended with lymph, with a reddish areola, which becomes very wide. The areola begins to fade on the tenth day, the pustule begins to dry, and by the fourteenth day a brown mahogany scab or crust has formed, which is detached about the twenty-third day. The cicatrix is circular, depressed, radiated, and foveated, becoming, after a time, paler than the surrounding integument.

During the course of a vaccination, more or less constitutional disturbance occurs, especially in children.

Eczematous and papular eruptions often develop in strumous children, for which the virus is unjustly held responsible.

VARICELLA.

Synonym. Chicken-pox.

Definition. A mild, slightly contagious, febrile affection; characterized by a moderate fever, and the appearance of a *vesicular* eruption, drying up and falling off in from three to five days.

Cause. A peculiar poison; attacking only children; occurring sporadically and as an epidemic.

Symptoms. Moderate *fever*, thirst, anorexia, and constipation, followed by the eruption of *vesicles*, which rapidly dry, and within the week drop off, leaving a slight *pit*. *Pustules* almost never occur. Symptoms are so slight, that, were it not for the vesicles, the affection would be often overlooked. The eruption appears on the *body* and *extremities*, very rarely on the forehead and in the mouth.

Prognosis. Most favorable.

Treatment. Entirely symptomatic. If vesicles on the face, efforts may be used to prevent pitting.

ERYSIPELAS.

Synonyms. Erysipelatous dermatitis; the rose; St. Anthony's fire.

Definition. An acute, specific, infectious disease; characterized by a fever of low type, and a peculiar inflammation of the skin,

generally of the neck and face. This inflammation exhibits a marked tendency to spread, to induce serous infiltration and suppuration of the areolar tissue, and to affect the lymphatic vessels and glands.

Cause. A specific virus; a micrococcus, the *Streptococcus erysipelosus*. Feebly contagious. One attack predisposes to another. The etiology of idiopathic (medical) and traumatic (surgical) erysipelas are identical. *Incubation*, from two to seven days.

Pathological Anatomy. Erysipelas is a simple inflammation—a dermatitis. The visceral changes, if any occur, are of a septic character. Infarcts occur in the lungs, spleen, and kidneys. Septic endocarditis and pericarditis and pleuritis are found post-mortem. Acute nephritis may occur.

Symptoms. Onset sudden; a *chill*, followed by *fever*, which soon reaches 104° or 105°, *frequent pulse*, 100 to 130, coated tongue, *nausea* and *vomiting*, severe pains in the limbs, with epistaxis in adults and convulsions in children, and often *diarrhæa*.

Delirium is frequent, and in those of alcoholic habits it resembles delirium tremens.

The eruption soon follows the chill, beginning in red spots, which rapidly coalesce and spread; a sense of heat, tension, and tingling is caused by the great ædema, which presents a tense, shiny appearance, the swelling being so great at times as to close the eyes and distort the features. In many cases small vesicles develop, which may coalesce, forming blebs, of considerable size, containing a clear yellow serum. After five or six days the eruption begins to subside, the symptoms abate, the part affected remaining tender, and there occurs moderate desquamation.

During the height of the attack *albumin* appears in the urine so that the possibility of *uræmic* symptoms must be remembered.

When extensive infiltration into the areolar tissue occur, the swelling and tension become greater, and it is termed phlegmonous erysipelas.

When the *eruption spreads* to different portions of the body, it is termed *erysipelas ambulans*.

Complications. *Thrombosis* of the cerebral capillaries or sinuses, or as it is sometimes called, "erysipelas of the brain," is explained by the intimate anatomical connection of the facial vein with the pterygoid plexus and cavernous sinus.

Ædematous laryngitis, from extension to the larynx.

Pneumonia, pleurisy and meningitis are frequent complications.

Diagnosis. Not difficult. The fever, early spreading eruption, with burning, swelling, tension and tingling, and albuminous urine, separate it from the other *eruptive fevers* and *erythema*.

Prognosis. Usually favorable. Unfavorable if it attack drunkards; if it becomes gangrenous; if thrombosis of sinuses occur, or if it extends to the larynx.

The convalescence, even from the mildest attack, is slow, the patient continuing weak and anæmic for several weeks.

Treatment. Mildest cases only require a laxative, nourishing diet, and locally vaseline or bismuth oleate, to modify the heat and burning.

Prof. Da Costa strongly urges the use of *free purgation* before the use of the remedies usually *administered*.

According to Reynolds, aconitum will cut short an attack. He administers $\mathfrak{m}_2/\mathfrak{z}$ -j, every fifteen minutes for the first two hours; then in hourly doses, until the surface is moist and the temperature lowered. The author corroborates this plan, from a personal experience.

In severe cases, tinctura ferri chlor., gtt. xx-xxx, every third hour, well diluted. Also quinina gr. ij, every third hour. Ext. belladonnæ, gr. ¼, added, with benefit. The diet from the onset should be of the most nourishing character, and administered at regular intervals. Dr. Waugh strongly lauds extractum pilocarpi fluidum in erysipelas.

Prof. Da Costa reports excellent results in cases with rapid spreading tendency, from the use of pilocarpinæ hydrochloras, gr. ½, hypodermically or ext., pilocarpi fluidum, gtt. xx-xl, every two hours. Good results are obtained in a fair number of cases from potassii iodidum.

Cerebral symptoms, stimulants, opium and chloral.

Extension to throat, argenti nitras, brushed over parts. If symptoms of ædema of the glottis develop, tracheotomy is indicated.

Locally, soothing applications are indicated, to wit: Vaseline, ung. zinci oxidi, ol. olivæ cum glycerinæ, bismuth oleat. or ungt. hydrargyrum. Excellent results are obtained by the use of equal parts of ichthyol and lanoline, applied on gauze; if the face be the seat of disease, covering the part with a mask of gauze spread with the above unguentum.

In the *phlegmonous* variety, argenti nitras, \ni j, spts. ætheris nitrosi, \exists ij, brushed over and beyond the affected part, with the internal use of large doses of *quinina*, ferrum, and stimulants.

DENGUE.

Synonyms. Break-bone fever; neuralgic fever; dandy fever.

The word dengue is pronounced dangay.

Definition. An acute, epidemic, febrile disease, consisting of two paroxysms of fever with an intermission. The first paroxysm is characterized by high fever, distressing pains in the joints and muscles, and a peculiar eruption; the second paroxysm is characterized by a milder fever, an eruption of different character, attended with intense itching, by some recurrence of the joint pains, and by debility.

Cause. Unknown; but it is evident that a peculiar condition of the atmosphere has some influence in its development. *Incubation*, from two to six days.

Symptoms. Onset sudden—fever, 103° to 105°, intense headache, burning pains in the temples, backache, severe aching and swelling of the joints and stiffness of muscles, nausea, vomiting, constipation and the appearance of a rash, resembling scarlatina, from which the disease has been mistaken for scarlatinal rheumatism. After some hours to two or three days, a distinct intermission obtains, of one or two days' duration.

The onset of the second paroxysm is also sudden, but the symptoms are much less severe, although the patient is greatly *debilitated*; it is at this time that the characteristic eruption appears, being either *erythematous* or *rubeolous*, and attended with *intense itching*, remaining for about two days, when desquamation occurs and convalescence is established, but is prolonged by the great debility of the patient. Average duration of the disease eight days. *Relapses are common*.

Diagnosis. Most apt to be mistaken for acute articular rheumatism, especially during the first paroxysm, but the course of the disease and the epidemic influence should prevent such an error.

The eruption might mislead for scarlet fever or measles, were it not for the severe joint and muscular pains.

On the first appearance of the pandemic of La Grippe in 1889 the

similarity of the early myalgic symptoms with those of dengue was particularly noticable.

Prognosis. Favorable.

Treatment. No specific. Entirely symptomatic.

At the onset, free purgation and diaphoresis.

For the fever, quinina, gr. v every five hours, or antipyrine, gr.x-xx, repeated p. r. n.

For the pains, opium or phenacetine.

For the itching, lotion of acidum carbolicum.

DISEASES OF THE MOUTH.

CATARRHAL STOMATITIS.

Synonyms. Simple stomatitis; erythematous stomatitis; catarrh of the mouth.

Definition. An acute catarrhal inflammation of the whole or a portion of the mucous membrane of the mouth and tongue, characterized by pain, redness, swelling, and disordered secretion. Most common in infants and children. Chronic stomatitis occurs mostly in adults, the result of alcoholic or tobacco excesses.

Causes. Introduction of hot and irritating substances into the mouth; difficult dentition; secondary to disorders of the stomach, to measles, scarlet fever, and variola.

Pathological Anatomy. The buccal mucous membrane and tongue have a dark red appearance, are much swollen, the tongue often appearing as if too broad to lie between the teeth, the sides showing the impressions of the teeth; the secretions are at first lessened, afterward increased, a turbid mucus covering the cheeks, gums, and tongue, thus giving a coated tongue.

Symptoms. Oral catarrh begins with the ordinary signs of inflammation, burning, smarting pain, and tension in the mouth, in those old enough to describe their suffering. Very young children refuse to nurse or allow their mouth to be touched, taking hold of the

nipple, giving one or two pulls and suddenly letting go and beginning to cry, have *slight fever*, disordered stomach, are *fretful* and *sleepless*, craving cooling drinks.

The sense of taste is blunted, and there is usually an unpleasant

bitter taste in the mouth.

If the catarrh becomes *chronic*, the breath has a fetid odor and the tongue is coated in the morning, the taste is disordered, and there is generally more or less depression of spirits.

Diagnosis. If the buccal cavity be examined, the condition is

readily discerned.

Prognosis. Recovery is the rule for the acute variety.

The *chronic* cases are usually due to the use of tobacco or alcohol, and are only modified by the absolute withdrawal of the exciting cause.

Treatment. The most important point in the treatment is the removal of the exciting cause, attention to the secretions and diet, and gently mopping out the mouth at frequent intervals with a soft wad of absorbent cotton and cold or iced water, or locally—

Sodii boratis,							
Aquæ destillat.,				٠		۰	f Z iss
Mel. rosæ,	۰						f 3 iss.

In severe or aggravated cases a dilute solution, argentum nitras (gr. ij-v, aquæ f3j) should be applied.

APHTHOUS STOMATITIS.

Synonyms. Follicular stomatitis; vesicular stomatitis; croupous stomatitis.

Definition. An acute inflammation of the follicles and mucous membrane of the mouth and tongue, characterized by a *fibrinous* or *croupous exudation*; the exudation first appearing in *isolated spots* (aphthæ discrete), afterward coalescing, and forming large and irregular-sized patches (aphthæ confluens), which rupture, leaving an ulcer, which slowly heals.

Causes. A disease principally of childhood. Difficult dentition; disorders of digestion; uncleanliness, such as neglect to rinse the child's mouth after nursing; a symptom of measles and diseases of the buccal cavity.

Pathological Anatomy. Begins as a small, whitish papulovesicular elevation, semi-transparent, hard and tender, with a distinct red zone about their base; there may be as few as six or as many as twenty; they may remain isolated (aphthæ discrete) or coalesce (aphthæ confluens); they are regarded as either a peculiar deposit or a local croupous exudation. After a day or two they rupture, leaving an irregular white or grayish ulcer, which slowly heals. The seat of the affection is the internal surface of the lips and cheeks, the gums, tongue, and roof of the mouth.

Symptoms. The condition begins with redness of the mucous membrane of the mouth, followed rapidly by the spots or vesicles on the inner surfaces of the lips, the edges of the tongue, and the cheeks; in infants, the pain is so severe that the child refuses to nurse; in older children, pain from talking, mastication, and deglutition; salivation is marked, the saliva dribbling from the mouth. There is slight feverishness, fretfulness, and sleeplessness. Digestion is impaired, and quite commonly diarrhwa occurs. A disagreeable, penetrating odor escapes from the buccal cavity.

Diagnosis. Impossible to confound with any other affection if the buccal cavity is examined.

Prognosis. Always favorable.

Treatment. Removal of the exciting cause. Attention to the dietary and the secretions is paramount. If constipation occur the use of a few powders of hydrargyri chloridum mite, containing $\operatorname{gr.}_{\frac{1}{12}}$, adding a small amount of sodii bicarbonas or small doses of pepsinum. Protracted cases require tonic doses of quininæ sulphas.

Locally, good results are obtained from strong solutions of potassii chloras, infusum coptis, or touching the ulcers with argenti nitras.

ULCERATIVE STOMATITIS.

Synonyms. Diphtheritic stomatitis; gingivitis ulcerosa.

Definition. An acute diphtheritic inflammation of the mucous membrane of the mouth, continuing until extensive and unhealthy ulcerations occur. It usually begins on the margin of the lower gums, and often extends to the lips, cheeks, or tongue.

Causes. Usually seen in children only. Most frequently in the

families of the poor, the result of unfavorable hygienic surroundings, personal uncleanliness, and poor food. Often seen in those reduced by severe acute disease. Perhaps contagious, as *epidemics* are not rare. Prevails in institutions, jails, and camps, in which the sanitary conditions are defective.

Pathological Anatomy. The gums first appear congested, swollen, bleeding readily, and separated from the teeth; soon a firmly adherent deposit in the form of patches appears, at first whitish, speedily becoming gray or even black, from disintegration, becoming soft and pulpy, the separated slough leaving irregular-shaped ulcers, with raised margins, from ædema of the surrounding tissue. They are not deep, and their surface is covered with a pulpy, yellowish substance. The morbid process usually extends to the inner side of the lips, cheeks, and to the tongue.

Symptoms. Begins with swelling of the mucous membrane about the base of the teeth, followed with pain aggravated by mastication or deglutition; food and drink must be of the blandest character. The mouth is hot, the saliva dribbles away, mixed with blood and shreds of pulpy matter, the breath is fetid, the appetite, digestion, and bowels disordered. The patient is feverish, fretful and sleepless.

There is always enlargement and tenderness of the submaxillary glands.

The affection is often associated with entero-colitis.

Diagnosis. Apt to be confounded with gangrenous stomatitis, than which, however, there are less constitutional symptoms and a slower course of the malady.

Prognosis. Favorable. If promptly and properly treated, the ulcerated surface rapidly heals, although quite commonly some teeth are lost.

Treatment. The etiology of the affection must be borne in mind and remedied. Strict attention to the diet, to the secretions, and absolute cleanliness.

Internally, the prompt use of potassii chloras, gr. j-v, frequently repeated, often acts like a specific. The general health frequently calls for quinina, ferrum, and stimulants.

Locally, a strong solution of potassii chloras, or keeping the ulcer covered with bismuth, or frequent applications of alumen exsiccatum

are valuable. Cases which resist these remedies should have applied the following combination, proposed by the late Dr. Dewees:—

R.	Cupri sulphat., .				٠					gr. x	
	Pulv. cinchonæ opt.	,		0					۰	3 ij	
	Pulv. g. arab.,	٠		0			٠			3 j	
	Mel. commun.,		0	۰		ď		۰	٠	fzij	
	Aquæ font.,		4	0		٠	0			f Z iij.	M.
Ft	. sol.										

Sig.—The ulceration to be touched twice daily, with the point of a camel's-hair pencil.

If a spreading tendency develop, the application of argenti nitras dilutus, or a diluted solution of acidum nitricum is indicated.

THRUSH.

Synonyms. Parasitic stomatitis; muguet; sprue; white mouth. Definition. An inflammation of the mucous membrane of the mouth, associated with or caused by the growth of a parasitic plant, the oidium albicans; characterized by pain, disorders of digestion and of the bowels.

Causes. The development of the thrush-fungus, ordium albicans, is promoted by all those conditions designated as unhygienic, by debilitated conditions of the general system, and by neglect to thoroughly rinse the mouth after nursing or bottle-feeding. It is claimed that a catarrhal stomatitis is the soil upon which the fungus develops.

The age is considered a predisposing cause, seldom being seen after two years of age. In adults, only toward the last stages of cancer or consumption.

Pathological Anatomy. The mucous membrane of the mouth presents a dark red appearance in isolated patches, on which whitish points appear, which rapidly coalesce into large areas. They closely resemble curdled milk, from their soft consistency. These whitish points consist of epithelium and fat, in which are embedded the sporules and filaments of the fungus.

The deposit first appears about the angles of the mouth, soon extending to all parts of the cavity, often to the pharynx and œsophagus.

The mouth is usually swollen and tender, the breath often fetid.

Symptoms. Pain, aggravated by nursing or mastication. The

lips are swollen, the saliva is increased, the breath hot and somewhat fetid. There is usually increased temperature. Diarrhaa is frequent, the stools green and sour, causing an erythema of the buttocks.

Diagnosis. The curd-like appearance of the deposit, showing the presence of the fungus upon microscopical examination, will prevent error. Should not be confounded with aphthous stomatitis, in which *ulcers*, preceded by the formation of vesicles, are perfectly distinctive.

Prognosis. Favorable, unless occurs toward the termination of exhausting diseases.

Treatment. Absolute cleanliness of the mouth is all important. *Internally*, remedies should be directed to the removal of the disorders of the gastro-intestinal tract.

Prompt relief has followed the use of *sodii hyposulphitis saturat*. *solut*., gtts. iij-x, every two or three hours, and the local application of the same solution.

Locally, solutions of sodii boras often answer every indication, the best vehicle being glycerinum, and not mel or saccharum, a good formula being—

Sodii boratis,											
Glycerini, .											2.5
Aquæ,		٠	۰	٠	۰	0	0	٠	٠	3 vj.	М.

Sig.—Thoroughly applied four or five times daily, and continued for a week after the disappearance of the affection.

GLOSSITIS.

Definition. An inflammation of the parenchyma of the tongue; characterized by great swelling of the organ, with difficult masticacation, deglutition, and vocalization.

The affection may be either acute or chronic.

Causes. The *acute variety* is usually the result of some direct irritation to the tongue, such as direct injury, contact of boiling liquids, the action of acrid or corrosive substances, or the sting of the tongue by an insect, such as the bee or wasp.

The *chronic variety* is generally circumscribed; it may follow the acute; be due to the sharp edges of the teeth, or the use of a tobacco pipe.

Pathological Anatomy. Acute glossitis begins with intense hyperæmia, redness and swelling of the organ; the size often be-

comes so great that the tongue is too large for the mouth, and thus protrudes between the teeth; its surface is covered with a thick secretion, and it becomes of a pale or grayish color. The swelling may rapidly decline, or abscesses may form, which leave a more or less decided depressed cicatrix.

Chronic glossitis occurs usually along the edges of the organ, the cicatricial changes being in circumscribed hard spots. If the entire tongue is affected with chronic inflammation, the action is superficial, and has been termed "psoriasis of the mouth."

Symptoms. Acute glossitis begins rather abruptly with fever, increased pulse, restlessness, anxiety, enlargement of the tongue, a sensation of heat in the mouth, with pain, and increased flow of saliva. Mastication and deglutition become difficult if not impossible, the voice muffled and dyspnwa decided. The glands at the angles of the jaw are enlarged, which, in turn, compress the vessels of the neck.

When *suppuration* supervenes, the constitutional symptoms become severe and the oral symptoms are intensified. *Death* has occurred from suffocation in severe cases.

Chronic glossitis presents pain as the chief symptom, aggravated by movements of the organ.

Diagnosis. The rapid course of acute glossitis should prevent its being mistaken for any other affection.

Chronic glossitis, if severe, might be mistaken for cancer of the tongue, although the slow and mild progress of the former contrasts strongly with the rapid, severe, and painful course of the latter, with its marked constitutional symptoms.

Prognosis. Acute glossitis usually terminates in recovery within a week, although the danger of suffocation must always be remembered.

Chronic glossitis is an incurable malady in the majority of instances.

Treatment. For acute glossitis prompt measures are demanded. For the fever and rapid pulse, tinctura aconiti, gtt. j to iij every half hour or hour until its physiological effects are produced.

For the *enlargement* of the organ, either *ice* constantly applied internally and externally, at the angles of the jaw, or the persistent use of *hot water* held in the mouth and externally; if prompt relief does not follow these measures, or if the case is an aggravated one, the prompt *deep scarification* of the tongue must be resorted to.

If abscesses form, promptly open them and administer quinina.

If suffocation appear imminent, tracheotomy must be performed.

For *chronic glossitis*, the removal of the exciting cause and the local use of *argenti nitras* to the ulcerated edges.

"For psoriasis of the tongue," the local use of argentum or acidum carholicum.

The general health must always receive due attention.

GANGRENOUS STOMATITIS.

Synonyms. Cancrum oris; noma; water-cancer.

Definition. An acute, rapidly progressive gangrenous ulceration of the mouth, leading to extensive sloughing and destruction of the affected tissues.

Causes. It is probable that gangrenous stomatitis is due to some parasitic micro-organism, but its character is as yet unknown. It attacks feeble and sickly children by preference; now and then observed in adults.

It is seen as a primary affection and as a sequelæ to measles, scarlet fever, typhoid and typhus fevers, and pneumonia.

Pathological Anatomy. The process is essentially a rapidly progressive moist gangrene.

Symptoms. Noma usually begins insidiously by the destructive process developing upon an ulcerative stomatitis, or the appearance of a sloughing ulcer on the gums or the inside of the cheek of an apparently healthy mucous membrane. Often the gangrenous odor is the first symptom noted. The cheek swells, becomes ædematous, and the skin waxy looking; within a day or two the process may spread, involving the whole side of the face, and as the ulcer becomes deeper and approaches in its progress the integument, the skin becomes red, blue, purple, black, or a combination of these shades, followed by the development of a bulla filled with ichorous fluid, the skin softening and breaking down.

The constitutional reaction is very severe; pulse rapid and feeble; temperature 102°-104° F.; extreme prostration; pain but little complained of, but the odor fills the house; diarrhæa is common, hemorrhages from the mouth rare. Death usually occurs in a week to ten days, the patient often presenting a frightful picture. Very rarely indeed recovery occurs.

Diagnosis. No other disease or condition can be confounded with gangrenous stomatitis.

Prognosis. Nearly all cases die.

Treatment. There is but little to say about the treatment of noma. Destruction of the ulcer by the use of argentum nitras in stick, fuming acidum nitricum, or the Paquelin cautery might be tried. Washes of antiseptic solutions, and the use of quantities of finely powdered acidum boric are useful. Keep up the strength of the patient with ferrum, arsenicum, quinina, and stimulants.

DISEASES OF THE STOMACH.

ACUTE GASTRIC CATARRH.

Synonyms. Acute gastritis; gastric fever; bilious fever; acute indigestion; subacute gastritis.

Definition. An acute catarrhal inflammation of the mucous membrane of the stomach; characterized by feverishness, loss of appetite, nausea, with occasional vomiting, painful digestion, irregularity of the bowels, and in severe attacks, vertigo (stomachic vertigo).

Causes. Deficient quantity of or quality in the gastric juice. Errors in diet, insufficient mastication of food, swallowing liquids which are either too hot or too cold, and particularly the abuse of alcoholic liquors.

Often secondary to infectious diseases, such as scarlet fever, measles, smallpox, diphtheria, and typhoid fever. Occasionally the result of sudden changes of temperature.

Pathological Anatomy. The mucous membrane is irregularly congested and engorged, and covered with a grayish, semi-transparent and tenacious mucus, having an alkaline reaction. The true gastric juice is secreted in lessened amount or is entirely suspended.

Symptoms. At first, loss of appetite, at times disgust for food, heavily coated tongue, bad taste and breath, persistent nausea, and at times, vomiting, first of undigested food, then viscid mucus, acid and

bitter, and finally, bilious matter; moderate irritative fever is present, with headache, considerable thirst, and flashes of heat with sensations of burning in the palms of the hands and soles of the feet; acid drinks eagerly sought after; digestion imperfect, giving rise to pain, tenderness, feeling of weight, and eructations; bowels often loose, sometimes, however, constipated. Vertigo with pain in the nucha, is a prominent symptom in many cases, causing great anxiety and depression of spirits. The urine is scanty, containing lithates and pigment.

The symptoms are aggravated by errors in diet, and if saccharine or fatty articles are taken, *hearthurn* occurs.

Toward the termination of an attack, herpetic eruptions appear about the mouth.

Diagnosis. Acute gastric catarrh with fever may be confounded with *remittent* and *typhoid fever* of the first week, but all doubts will disappear as these maladies develop.

The vertigo may be mistaken for cerebral disease, but the disappearance of this symptom when stomachic treatment is inaugurated removes all apprehension.

Prognosis. Favorable. Duration about a week; recovery slow, even under treatment, as far as perfect digestion is concerned.

Treatment. Give the stomach as complete a *rest* as possible, and as anorexia is a prominent symptom, the error should not be made of insisting upon the patient eating for a day or two at least.

If the stomach is overloaded, a rare incident, an *ipecac emetic*, or *apomorphine*, gr. 1/6, by hypodermic injection, is indicated, or, if vomiting has begun, it may be encouraged by swallowing large draughts of *hot water*, which will act as a sedative if the stomach be empty.

The majority of cases do better by an active purgation with either hydrargyri, chloridi mite, gr. v-x, with sodii bicarbonas, gr. v, followed in six or eight hours with an ounce dose magnesii sulphas, or a full dose of Hunyadi-Janos water; or small doses every two hours of powders containing—

Every two hours, followed the second morning after the last powder with a saline.

After the stomach and bowels have been thoroughly cleansed the diet may be more liberal, and some one of the following drugs used;

tinctura nucis vomicis, gtt. v-x-xv, well diluted, every four hours, or pepsinum and bismuth, or papoid. Weak alkaline mineral waters or liquor calcis, should be freely used. After the acute symptoms have subsided—

Be101	<i>re</i> meal	s, dili	ited, v	WIII 1	mI	orc	ve	th	e:	app	pet	ite	a	\mathbf{n} d	digestion.	

ACUTE GASTRITIS.

Synonym. Toxic gastritis.

Definition. An acute and violent inflammation of the mucous, submucous, and muscular coats of the stomach, with loss of tissue; characterized by great pain, constant vomiting of blood-streaked or bloody mucus, whatever may be ingested, and symptoms of collapse.

Causes. Ingestion of irritant and corrosive poisons, such as the mineral acids, arsenic, corrosive sublimate, copper, and carbolic acid.

Pathological Anatomy. The mucous membrane is vividly red and injected, more marked at some portions than at others; it is soft and friable; erosions are irregularly scattered, and the submucous, muscular, and at times serous coats show decided destructive changes. The gastric tubules are destroyed in large numbers. In many cases the *oral* mucous membrane presents signs of severe inflammation.

Symptoms. Immediately or soon after swallowing the irritant, there ensues a deadly nausea, with rapid and persistent vomiting; first, of the contents of the stomach acted upon by the poison, afterward, shreds of mucous membrane and blood clots; there are also present great anxiety and depression, a weak, rapid pulse, slow and shallow respiration, cold skin, covered with a cold sweat, intense burning heat at the epigastrium, thirst with burning in the fauces and gullet, and exhaustive purging; the features are more or less retracted or sunken; these symptoms terminating in collapse and death, or slow convalescence and recovery with a crippled stomach.

A diagnosis of the character of the poison swallowed is often afforded by the stain of the lips, face, and mucous membrane, to wit: sulphuric acid, blackish eschar; nitric acid, yellowish eschar; caustic

potash, spreading widely and softening the tissues; corrosive sublimate, whitish or glazed; carbolic acid, white and corrugated.

Prognosis. Very grave. Many perish from shock, and the destruction of the mucous membrane of the stomach, which prevents nourishing. Early treatment when no perforation of the walls of the stomach has occurred and recovery is possible, the organ being ever after much weakened.

Treatment. At once, hypodermic injection of morphina, repeated at regular intervals.

Vomiting should be encouraged by the free use of demulcents.

If the case be seen within a short period of the swallowing of the poison, the proper antidote should be used, but if some hours have elapsed, it is useless. *Ice*, internally and externally, gives great relief. The stomach should be washed out with the stomach pump, thereby removing any remaining poison, while at the same time it acts as a sedative to the inflamed membrane. *Bismuthi subnitras*, grs. xx-xxx every hour or two, is beneficial.

Milk and lime-water is the only food that should be given by the stomach, enemata being used to support the system.

CHRONIC GASTRIC CATARRH.

Synonyms. Chronic gastritis; chronic dyspepsia; drunkards' dyspepsia.

Definition. A chronic catarrhal inflammation of the stomach, with thickening of the coats and atrophy of the gastric glands; characterized by tenderness over the epigastrium, impaired appetite, painful and imperfect digestion, thirst, and great depression of spirits or melancholia.

Causes. Repeated attacks of acute gastric catarrh; habitual and excessive use of spirituous liquors, tea, coffee, and the free use of icewater during and between meals; improperly prepared and unsuitable food; irregularity of meals and imperfect mastication; excessive tobacco-chewing; malaria; disease of the heart, lungs, pleura, liver or kidneys, producing chronic congestion of the stomachic vessels; cancerous or other degenerative diseases of the stomach.

Pathological Anatomy. The mucous membrane is of a brownish or slate color, elevated into ridges from hypertrophy, the result of constant congestion; the peptic glands first increase in size, then un-

dergo granular change, atrophy of their cells resulting. The mucous membrane is covered with a thick, alkaline, tenacious mucus. Ewald describes the minute anatomy as that of a parenchymatous and interstitial inflammation, which may lead to such widespread degeneration of the glandular elements that ultimately scarcely a trace of secreting tissue remains. These changes may affect the entire organ or be limited to portions of the stomach.

Symptoms. The persistent and manifold symptoms of indigestion, varying somewhat with the extent of the mucous surface and secreting glands involved, are the first indications of the disease, such as loss of appetite, disagreeable feeling of gnawing and at times fullness in the stomach, tenderness at the epigastrium, but slightly influenced by eating, prominence of the epigastrium, from distention by decomposing gases, occasional nausea and vomiting after meals, of undigested food, or, when the stomach is empty, of colorless fluid. A colorless vomit joined to symptoms of long-continued indigestion is always very characteristic of chronic gastritis. Drunkards suffer from an early morning vomit consisting of glairy mucus and saliva swallowed during sleep, raised only after great retching. The tongue is usually heavily coated, although it may be clean; thirst is often constant, water and more frequently stimulants being craved; burning at the pit of the stomach and under the sternum (heartburn) is very common, the bowels are constipated, the urine high-colored and contains an excess of phosphates or urates, or exhibits crystals of oxalate of lime. The circulation is feeble, there is depression of spirits amounting in some instances to delusional melancholia; sleeplessness is persistent, and occasionally there are attacks of vertigo (stomachic vertigo), which greatly alarms the patient. All these symptoms result from either a deficient secretion of the gastric juice or from a lessened proportion of hydrochloric acid in the juice secreted, and also from the excessive mucus and from diminished peristalsis of the stomach, these morbid conditions favoring the fermentation and decomposition of the food. Follicular pharyngitis of an aggravated type adds to the general distress of the patient. The imperfect digestion causes more or less loss of flesh, the fat disappearing, the muscles relaxed and the skin dry, harsh, and of a dirty-pale color, and not infrequently eczema and other cutaneous diseases result.

Diagnosis. Chronic gastritis is associated with so many chronic diseases that a correct diagnosis is of great importance. Among the affections likely to lead to error in diagnosis are gastric ulcer, gastric

cancer, gastric dilatation, cerebral vertigo, cardiac disease, and disease of the kidneys and liver.

Prognosis. Complete recovery is hardly to be expected, but great amelioration of symptoms occur and with guarded diet and mode of life good health may be enjoyed for many years.

Treatment. The first indication is the correction of the *indigestion*, which is usually the most pronounced and distressing symptom; this is accomplished by carefully regulating the amount and character of the food used, avoiding fatty, saccharine, and starchy articles or highly seasoned food or stimulants. A milk diet is beneficial, to which may be added beef in small amounts, eggs, oysters, and a few fresh green vegetables.

The second important symptoms to correct are the *constipation*, which is often most obstinate, and *clearing* the stomach of the tenacious mucus which neutralizes what gastric juice is secreted. Appropriate purgatives are the natural mineral waters, such as Bedford Water, Saratoga, or Hunyadi Janos, or—

Magnesii sulph.,									
Sodii et potass.									
Acid. tartaric.,		۰	٠	۰	٠	0	0	gr. xx.	M.

Dissolved in a glass of water and drunk, effervescing, an hour before breakfast.

An excellent purgative and promotor of stomachic peristalsis is:—

Ŗ.	Extrac	eti rhar	nni purs	hia	næ	e flo	d		 	. f 3 j	
			vomicæ,								
	Aquæ	chloro	formi, .					 ٠		. f z j.	М.
Cra	0	1		Sa.	3-	-6.		 1	 11	3:1	

SIG.—One to two teaspoonfuls after meals, well diluted.

For the purpose of *cleansing* the stomach of the tenacious mucus as well as for its stimulating action on the glands *lavage* or irrigation of the stomach with lukewarm water is valuable. The water can be medicated with a solution of salt, or sodii bicarbonas or acidum boric. Ewald considers the morning, on an empty stomach, the preferable hour for the practice of stomach washing.

For patients who object to lavage great relief follows the systematic drinking of one-half to one pint of *hot* water an hour *before* meals.

For the irritable condition of the mucous membrane, associated with poor appetite and slow digestion, good results are reported from *strontii bromidum*, gr. x-xv, well diluted, before meals.

To aid digestion, acids, pepsin, pancreatin, papoid and bitters are of value, the following being an excellent prescription:—

R .	Pepsini (cryst), .											
	Acid. hydrochlorici	dil	. ,		۰	٠				٠	fziv	
	Glycerini,										f z iv	
	Strychninæ sulph.,										gr. ss	
	Aquæ chloroformi,						q.	S.	. a	d	fžiij.	М.

For the morbid condition itself may be used, liq. petassii arsenitis, gtt. j-ij before meals, or bismuth subnit., gr. x-xx, on a comparatively empty stomach, one hour before or two or three hours after meals; it may at times be combined with sodii bicarbonas. Argenti nitras, gr. ½-½, or argenti oxidum, gr. ½-j, in pill, before meals, or acidum hydrochloricum dilutum, gtt. x-xx, in water, before meals, are useful remedies.

Pain is so severe in some cases that resort must be had at times to opium or belladonna in small doses, after meals. Cocainæ hydrochloras, gr. 1/6, is also recommended.

Rest of the body and mind is almost as imperative as rest of the stomach.

GASTRIC ULCER.

Synonyms. Peptic ulcer; chronic gastric ulcer; perforating ulcer.

Definition. A solution of continuity, involving the mucous membrane and one or more layers of which the walls of the stomach are composed; characterized by pain, disorders of digestion and vomiting of blood.

Causes. There is no generally accepted view of the etiology. Ewald attributes it mainly to an "altered composition of the blood, and the resulting insufficient nourishment of the cells." Riegel claims that the ulcer is due to a self-digestion of the stomach at a limited spot, and it is certainly more than a coincidence that in ulcer the gastric juice is always hyperacid. More common in young females than males. Anæmia or its sequelæ a chief factor. Disorders of menstruation; blows over the epigastrium; burns of the integument; syphilis; tuberculosis. Virchow claims that emboli or thrombi form in the nutrient gastric arteries which have lost their tonicity, an ulcer forming at the point of obstruction.

Pathological Anatomy. In the majority of cases the ulcer is

solitary. The posterior wall near the pylorus is the most frequent location.

In a typical case there is a circular hole, with sharp borders in the serous coat of the stomach; the loss of substance is greater in the mucous membrane than in the muscular coat, and greater in this than in the serous coat, so that the ulcer looks like a shallow funnel, the apex at the outer wall, the base at the inner wall of the stomach; it is first round, growing, becomes elliptical, bulging at portions, becoming irregular; size, from ½-½ inch in diameter. When the ulcer heals before all the coats are perforated, a distinct cicatrix marks the location. During its progress nutrient vessels are eroded, causing profuse hemorrhage. Chronic gastric catarrh complicates the majority of cases.

Symptoms. More or less prominent symptoms of indigestion. Pain constant at the "pit of the stomach," increased by taking food, especially of an irritating character, the pain often felt in the back, of a burning, gnawing character. Tenderness at one or more points, extending from the front to the back. Vomiting is almost as constant as pain, coming on soon after eating if the ulcer is at the cardiac orifice, an hour or so after it is located at or near the pylorus. Rejected matter may be undigested or partly digested food, or simply acrid mucus. Vomiting of blood in large quantities and arterial in color is almost diagnostic of gastric ulcer; the blood may be dark in color if it has remained in the stomach some time before being rejected.

Severe and frequent attacks of gastralgia may add to the suffering of the patient. The general condition of the patient is not significant, some being greatly debilitated, while in others the nutrition is but little deranged.

Duration. The ulcer is slow in forming, and runs a very chronic course, an average duration being, perhaps, a year. Cases are recorded in which the disease has suddenly developed and terminated by *perforation*, *peritonitis*, and *death* within two weeks, but such cases are rare.

Diagnosis. Duodenal ulcer presents symptoms so akin to those of gastric ulcer that a differential diagnosis is impossible.

Chronic gastritis is often confounded with gastric ulcer; the distinctive points are, absence of vomiting of blood, no localized constant pain aggravated by food, and no tenderness in the back; while the symptoms of indigestion are marked and persistent, with, as a

rule, a history of spirit drinking, and the age of the patient—middle life; ulcer in the young.

The points of distinction between gastric cancer and gastralgia will be pointed out when considering those affections,

Prognosis. Not very unfavorable. Recoveries are frequent. The dangers are perforation, peritonitis, or fatal hemorrhage.

Treatment. Give the stomach as complete a rest as possible; this is accomplished by *rectal* alimentation, or where it cannot be carried out, an exclusive *milk* diet, adding *lime-water* to enable the stomach to better retain the milk, or a strictly skimmed-milk diet, to which may also be added lime-water; the amount of milk should be one or two ounces every two hours. *Rest in bed* is paramount, and should be enforced.

For pain, small doses of morphina should be used as needed.

For hemorrhage, hypodermic injections of ergota are most reliable. Plumbi acetas, gr. j-iij, arrests the bleeding and exercises a favorable influence over the ulcer.

For the *ulcer*, *liquor potassii arsenitis* gtt. j-ij every five hours, has given excellent results in several cases treated by the author; *bismuthi subnitras*, gr. xx-xxx, combined with *sodii bicarbonas*, gr. iij-v, three times a day, often does well; *argenti nitras*, gr. ½-½, every four hours, or *argenti oxidum*, gr. ss. every four hours, are at times beneficial.

For the associated anæmia, *ferrum* and *arsenicum*, alone or combined, are indicated. Ferri albuminate would seem to be particularly indicated, or the following:—

The bowels must be kept soluble.

If perforation and peritonitis result, full doses of opium are indicated.

GASTRIC CANCER.

Synonyms. Cancer of the stomach; gastric carcinoma.

Definition. A peculiar malignant growth, occurring for the most part at the pyloric extremity of the stomach, making constant progress, destroying the gastric tissues and infecting the lymphatic glands; characterized by disorders of digestion, pain, vomiting, marked anæmia, and terminating in all cases by the death of the patient.

Cause. Hereditary. Develops after forty years, for the most part. The question of a cancer germ is gaining ground.

Pathological Anatomy. Cancer of the stomach is the most common form of cancer. It is, as a rule, a primary cancer. The variety is most commonly the *scirrhus*, next in frequency, *medullary*, the least frequent, *colloid*. As regards the location, eighty per cent. occur at the *pylorus*.

It originates usually in the *tubules*, rapidly infiltrating the remaining tissues, thickening everywhere as it progresses, and either remains a hard nodulated mass or undergoes ulceration. The hard nodulated growth at the pylorus constricts the orifice, resulting in dilatation of the stomach. The lymphatic glands adjacent to the stomach are infiltrated, secondary cancers resulting. Ulceration into an artery causes hemorrhage into the peritoneum, resulting in local peritonitis.

Complications. Fatty heart; thrombosis; tuberculosis.

Symptoms. The development of gastric cancer is insidious with *indigestion*, progressive in character, associated with *marked acidity*, *flatulency*, and a fetid breath.

The majority of cases have *vomiting*, occurring immediately after eating, if at the cardiac orifice, and some hours after if at the pylorus; if much dilatation of the stomach develop the vomiting occurs some days after eating. The rejected matter is food in various stages of digestion, associated frequently with *black grumous masses* of altered blood and tissues. Hemorrhage is frequent, rarely profuse, usually oozing of blood altered into a dark brown or black color—"coffee-ground" vomit.

Absence of hydrochloric acid in the stomach is a very constant observation in gastric cancer. Pain, marked and constant, dull, heavy, increased by pressure or food, seldom lancinating. Marked anæmia and emaciation are present, the surface having an earthy or fawn color. Edema of the ankles is an early diagnostic symptom in carcinoma of the stomach, often occurring as early as the third month, and may progress to a general anasarca. A tumor is found in three-fourths of the cases, occupying the epigastric region, not moving with inspiration. As the carcinoma progresses, the lymphatic glands enlarge, particularly the supra-clavicular and inguinal

glands. Jaundice frequently occurs, and the liver is enlarged. The urine often contains albumin.

The duration of the disease is about one year, the patient dying from *exhaustion*, *peritonitis*, or *hemorrhage*, the mind clear but despondent.

Diagnosis. The continuous presence of free hydrochloric acid in the stomach is a diagnostic sign of great value in excluding the probable existence of gastric cancer. Chronic gastric catarrh differs from gastric cancer, in the absence of a tumor, bloody vomit, characteristic pain, peculiar color of the surface, dropsy and the rapid emaciation.

Gastric ulcer differs in the character of the pain, age of the patient, large amount and color of bloody vomit, the absence of a tumor, and progressive emaciation. Still the diagnosis is often difficult.

Abdominal tumors may raise the question of a gastric cancerous tumor; the points of distinction are the characteristic symptoms of gastric cancer, and that abdominal tumors, especially of the liver and spleen, the ones most apt to cause error in diagnosis, are influenced by inspiration, while tumors of the stomach are not so influenced.

When a scirrhus of the pylorus lies upon the aorta, a pulsation may be communicated to it, raising the question of aneurism of the abdominal aorta, but the expansile pulsation of aneurism (Corrigan's sign) is wanting, as are the other symptoms of the affection, and if the patient is made to rest upon his hands and feet, the stomachic tumor falls away from the aorta and pulsation ceases.

Mikuliez claims that, by the use of his gastroscope, regular rhythmical motions can be seen when the pylorus is not the seat of cancer, and that such movements are absent when it is the seat of cancer.

Prognosis. Unfavorable. Internal medication offers no hope, the patient usually succumbing from starvation.

Gastric carcinoma occurring under thirty years of age is rapidly fatal, not conforming to the usual symptoms as seen later in life; the characteristic cachexia is commonly absent and hæmatemesis is rare.

Treatment. We possess no means of arresting the disease, although it is but fair to mention that in Germany *condurango* in the form of decoction is recommended as a specific in some cases. I have faithfully used the fluid extract with some benefit for the accompanying gastritis, but without effect on the tumor. "Six operations have

been practiced for the relief of stenosis of the pylorus: 1st. Pylorectomy; 2d. Gastro-enterostomy; 3d. Gastrectomy; 4th. Gastrostomy; 5th. Duodenostomy; 6th. Digital divulsion of the pylorus." Professor Billroth has excised the pylorus, thereby prolonging life ten months.

For acidity and fetor of the breath, acidum carbolicum, gr. ¼-½, or carbo animalis purificatus, gr. x-xxx, affords some relief.

For vomiting, bismuth and opium, or lavage or the washing out of the stomach.

For pain, morphina, or the following, recommended by Osler:

	Morphinæ sulph., Sodii bicarb., Bismuth subnit.,	٠	٠	۰			٠	gr. v	м.
Sig -	Reneated n. r. n.								

Avoid stimulants.

GASTRIC DILATATION.

Synonyms. Gastrectasis; pyloric obstruction; pyloric stenosis. Definition. An abnormal increase of the cavity of the stomach, with the walls either hypertrophied, or decreased in thickness; characterized by pronounced indigestion, vomiting of partly digested and partly decomposed food at intervals of a day or two, and noisy moving of flatus within the abdomen (borborygmus).

Causes. Most common cause a stricture of the pylorus, the result of cancer; pressure of tumor against the pylorus, preventing exit of stomachic contents. Loss of muscular tone, occurring in anæmia. Prof. Bartholow cites cases resulting in excessive beer-drinkers, who drank thirty to forty glasses of beer habitually, every day.

Pathological Anatomy. When obstruction exists at the pylorus, the whole organ is dilated, with hypertrophy of the muscular layer of the stomach. In dilatation without pyloric obstruction, the muscular layer is thinner than normal, paler in color, and presents signs of fatty degeneration; the mucous membrane is also pale, thin, and without rugæ.

Symptoms. Those of the disease producing the obstruction *plus* those of obstinate chronic gastric catarrh, with *characteristic vomiting*; the cavity having a greatly increased capacity, large accumulations take place, which are rejected every day or two, partly digested and partly decomposed. *Regurgitation* of partly digested aliment, acrid,

acid, and offensive, is very common. Bowels constipated, the stools hard and dry.

Physical signs of gastric dilatation are: on inspection, abnormal prominence of the whole epigastric region, with a tumor in the pyloric region which seems to be connected with the stomach; percussion, if empty, tympanitic note extending to or below the umbilicus, having a metallic quality; if the stomach be filled, high-pitched flat note; auscultation, splashing and rumbling sound, the succussion sound being distinct if the body be shaken.

Diagnosis. Copious vomiting of food partly digested, once in twenty-four hours or less often, epigastric distress and pain resulting from foul smelling and acid eructations and from obstinate constipa-

Penzoldt's modification of Piorry's method of determining gastric dilatation is to withdraw the contents of the stomach by means of the cosophageal tube and then refilling the stomach with fluid. By noting the lower limit of percussion dullness thus produced, the lower border of the stomach can be accurately determined.

Treatment. Regulated diet. Restrict the use of fluids, using a "dry diet" exclusively.

If the result of pyloric stenosis, one of the operations mentioned for pyloric cancer may be indicated.

Regardless of the cause, washing out the stomach with the stomach tube, every day or two, gives relief, and, if no stricture be present, administer *strychnina* or *nux vomica*, and very favorable results may follow.

GASTRIC HEMORRHAGE.

Synonyms. Hæmatemesis; gastrorrhagia.

Definition. Gastric hemorrhage is not, strictly speaking, a disease, but a *symptom*; still, vomiting of blood occurs under such a variety of conditions, that a separate consideration is desirable.

Causes. Ulcer of the stomach; cancer of the stomach; scurvy; purpura; hæmophilia; hemorrhagic malarial fever; congestion of the liver or spleen; vicarious at menstrual period; yellow fever; toxic gastritis.

Symptoms. Added to the symptoms of the cause of the hemorrhage, are a feeling of faintness and sinking at the pit of the stom-

ach, followed by the ejection of blood of a black, grumous, or coffeeground appearance. Rarely, and then generally in gastric ulcer, the ejected blood may have a bright red appearance, the gastric juice not having had time to act upon it. If the amount of blood escaping into the stomach is large, blood will be voided by stool.

Diagnosis. Hemorrhage from the lungs may be confounded with gastric hemorrhage. In the former, the blood is red, is coughed up, not vomited, and is associated with a history of pulmonary disease. The chief point of distinction between pulmonary hemorrhage and the vomiting of red blood is, that in the former you can discern rales on auscultating the chest, and they are absent in the latter.

Prognosis. Depends entirely upon the cause, the most unfavorable being the result of either gastric ulcer, or cancer, or hæmophilia.

Treatment. Complete rest in bed. *Ice*, internally and applied in bladders over the epigastrium and along the spine, or *hot water*, as hot as can be borne, in quantities of four to six ounces at very frequent intervals.

Hypodermic injections of morphina quiet the patient's fear, and at the same time have a constringing effect upon the vessels. Extractum ergotæ fluidum or ergotin hypodermically after the patient is quieted, or liquor ferri subsulphatis, gtt. j-v, well diluted by stomach.

Cases resulting from congestion of the liver or spleen are benefited by saline purgatives.

Allow no food by the stomach for several days, nourishing the patient by rectal alimentation.

The hemorrhage controlled, the future treatment is guided by the exciting cause.

GASTRALGIA.

Synonyms. Cardialgia; gastrodynia; stomachic colic; spasm of the stomach; neuralgia of the stomach.

Definition. A painful condition of the sensory nerves of the stomach, induced by various sources of irritation; characterized by violent paroxysms of gastric pain and spasm, associated with feeble cardiac action, and symptoms of collapse.

Causes. The affection belongs to the group of neuralgiæ. The most important factor in its causation is general nervous depression; other causes are gastric cancer or ulcer, malaria, rheumatic or gouty

diathesis, anæmia, and certain articles of diet. Occurring in chronic nervous affections, the so-called "gastric crises."

Symptoms. Like most neuroses, gastralgia is distinguished by its *paroxysmal* character. *Romberg* thus describes an attack:—

"Suddenly, or after a feeling of pressure at the præcordium, there is severe griping pain in the stomach, usually extending to the back, with a feeling of faintness, a shrunken countenance, cold hands and feet, and an intermittent pulse. The pain becomes so excessive that the patient cries out. The epigastrium is either puffed out, like a ball, or retracted, with tension of the abdominal walls. There is often pulsation in the epigastrium. External pressure is well borne, and not unfrequently the patient presses the pit of the stomach against some firm substance, or compresses it with his hands. Sympathetic pains often occur in the thorax, under the sternum, and in the æsophageal branches of the pneumogastric, while they are rare in the exterior of the body."

"The attack lasts from a few minutes to half an hour or longer; then the pain gradually subsides, leaving the patient much exhausted; or else it ceases suddenly, with eructation of gas or watery fluid, or with vomiting, and with a gentle, soft perspiration, or with the passage of reddish urine."

Besides such severe attacks, we often see painful sensations in the epigastrium, of various degrees of intensity, with passing faintness or sinking at the "pit of the stomach."

Diagnosis. From myalgia of the abdominal muscles, by the pain of gastralgia being more acute and lancinating, accompanied by nausea and vomiting and the absence of tenderness on pressure.

From intercostal neuralgia, by the fact that in this affection the pain is in the left hypochondrium, with painful spots along the course of the nerve trunk and at the spine, and absence of nausea and vomiting.

From gastric cancer, by the age, character of the vomited matter, constancy of the pain, the cachexia, emaciation, and the tumor.

From gastric ulcer, by the localized pain and its constancy, with tenderness and vomiting of blood, and constant dyspeptic symptoms, which is not the case in gastralgia.

Prognosis. As to perfect recovery, unfavorable, but not dangerous to life. A chronic affection, in that attacks are prone to return from time to time. The cause has much to influence a radical cure.

Treatment. For the paroxysm, hypodermic injections of morphina, gr. $\frac{1}{12}$ - $\frac{1}{14}$, or the stomachic administration of the "compound of anodynes," the so-called chlorodyne, in doses of mx-xxx p. r. n. The relief afforded by opium in some form is so decided that it is apt to lead to the opium habit when the attacks are frequent. Salicinum is a valuable remedy in this as in many other forms of neuralgia.

In the interval, regulated diet and one or more of the following remedies: argenti nitras, quinina, arsenicum, bismuth salicylas, ferrum, liquor iodii comp., or small doses of potassii iodidum.

ATONIC DYSPEPSIA.

Synonyms, Dyspepsia; indigestion; heartburn; pyrosis.

Definition. A functional derangement of the stomach, with either deficient secretion in the *quantity* or *quality* of the gastric juice; characterized by disorders of the functions of digestion and assimilation and the presence of sympathetic nervous symptoms.

Causes. Imperfect mastication; bolting of food; eating large quantities of food; same diet long continued; depressed nervous system, from worry and fatigue; sedentary habits or occupations. It is often inherited.

Symptoms. Perverted appetite, capricious or lost; difficult digestion, a feeling of weight or fullness in the epigastrium; acidity, from the decomposition of albuminoids; heartburn, flatulency, regurgitation, or vomiting of portions of partly digested food or acrid fluid—water brash or pyrosis. Pain or soreness at the "pit of stomach" during digestion. Tongue either clean or broad, flabby and pale, showing marks of the teeth. Bowels constipated; urine generally scanty and high-colored, with excess of urates or oxalates, or, in persons of nervous type, it is pale, of low specific gravity, and contains phosphates. Drowsiness after meals, with wakefulness at night, defective memory, headache, and absent mental vigor, with flashes of heat, followed by more or less perspiration. Palpitation of the heart with irregularity in rhythm.

Varieties of Dyspepsia.—I. Nervous dyspepsia, atonic form, seen in active business or busy professional men, especially those of thin, spare build, of nervous temperament, who eat meals rapidly and hurry off to their business. These cases present all the marked

M.

nervous phenomena. II. Flatulent dyspepsia, seen in hysterical individuals, and showing immense development of gas throughout the abdomen, associated with vertigo and mental worry or hypochondria. III. Acid dyspepsia, water-brash. Seen when the diet is coarse. Acidity of the gastro-intestinal canal and of the urine. IV. Irritative dyspepsia. Vomiting a prominent symptom. In these cases the tongue is small, red, and pointed.

Prognosis. With careful living, dyspepsia, functional in character, is curable. It has been aptly termed "remorse of the stomach."

Treatment. The most important indication is to regulate the diet. Forbid saccharine, starchy, or fatty articles of food. Eat small amounts at a time. Perfect insalivation and mastication. Rest after eating, from a half to an hour. Allow but small quantities of liquids with the meals. In the vast majority of cases forbid the use of stimulants with the meals.

Aid digestion with pepsinum, with or without acidum hydrochloricum dilutum.

Stimulate stomachic peristalsis with nux vonica, gentian or cinchona. For acidity, alkalies at time of acidity.

For flatulency, carbo animalis purificatus, gr. x-xx, or one or more of the carminatives, with tinctura nucis vomica before meals.

For pyrosis, bismuth and pulvis aromaticus, in large doses.

For vomiting, sodii bromidum in small doses, or acidum carbolicum, gr. 16-14, three or four times daily, or chloral hydrate, gr. x-xv, in demulcent by mouth or rectum, repeated p. r. n.

For constipation, resina podophyllum at bedtime, or Hunyadi Janos water before breakfast, hot.

For anæmia, massa ferri carbonatis or ferri lactas.

Irrigation of the stomach or lavage often gives remarkable relief. The drinking of *hot water* one-half to one pint an hour before meals is of benefit.

A homely but efficient combination for atonic dyspepsia associated with scanty, acid urine and constipation, is—

R.	Sodii bicarbonatis,						
	Tinct. nucis. vomicæ,						. f 3 iv
	Tinct. capsici,	۰	٠				. f3j
	Tinct. rhei.,			0	۰		. f Z iss
	Inf. gentian. comp., .					ad	fǯ vj.

Sig.—Half tablespoonful after meals, in water.

DISEASES OF THE INTESTINAL CANAL.

INTESTINAL INDIGESTION.

Synonym. Intestinal dyspepsia.

Definition. A derangement in the functions of intestinal digestion, resulting in the more or less complete decomposition of the *chyme*, caused by defects in the pancreatic, biliary, or intestinal secretions, or from deficient peristalsis, one or more of these, singly or combined; characterized by abdominal pain, distention and tympanites developing some hours after meals and nervous perturbation, anæmia and emaciation.

Causes. Imperfect diet; over-eating; anæmia; deficient exercise; worry; immoderate use of tobacco or stimulants; diseases of the stomach, intestinal tract, liver, or pancreas; malaria. Frequently inherited.

Symptoms. Intestinal indigestion may be either acute or chronic, the latter the more common.

Acute variety, the result of an irritant in the duodenum, rapidly developed pain, flatulency, borborygmi, slight feverishness, coated tongue, loss of appetite, headache, pains in the limbs, usually terminating in a mild attack of diarrhæa.

If the attack develops rapidly, the sudden formation of gases causes a paroxysm of *colic*.

Severe attacks are associated with disordered hepatic function, light-colored stools, slight jaundice, and high-colored urine.

Chronic variety, resulting from a greater or less decomposition of the partly altered food from the stomach. Pain, varying in character, occurring from two to four or six hours after meals, with slight tenderness and some fullness in the right hypochondrium, epigastrium, or the umbilical region. Tympanites and borborygmi are marked, the result of gaseous accumulations which have developed from the decomposition of the intestinal contents. Dyspnæa, the result of pressure against the diaphragm, is of frequent occurrence. Marked nervous phenomena develop, the result of the anæmia from deficient assimilation and from the depressing influence on the nervous system of the absorption of the "gases of decomposition."

or ptomaines; depression of spirits, hypochondriasis, sleeplessness, disturbing dreams, headache, vertigo, buzzing in the ears, muscæ volitantes, deficient mental application, cardiac irritability, numbness and tingling in the extremities, anomalous pains throughout the body, and in extreme cases, attacks of fainting or epileptiform and cataleptic attacks.

The *skin* is harsh and dry, the *bowels* are sluggish or *constipated*, the *urine* is high colored, of increased density, decidedly acid, and, on cooling deposits lithates, uric acid and oxalate of lime crystals.

Functional derangement of the liver follows after a time, adding to the general distress.

Anæmia and emaciation result if the attack be protracted.

Diagnosis. With our present knowledge it is usually impossible to designate forms of intestinal indigestion due to defects in the quantity or quality of either the pancreatic, biliary or intestinal secretions.

Acute intestinal indigestion differs from gastric indigestion in the time of development of the various phenomena, in the latter the symptoms appearing almost immediately after meals, while in the former not appearing until two, four or six hours after.

Chronic intestinal indigestion may mislead the physician if the various nervous phenomena are of a marked character, and a careful history of the case is not developed.

Prognosis. Favorable if proper and early treatment be inaugurated, unless the result of an organic lesion.

Treatment. Acute variety, the result of undigested food, is best treated by opium in some form, to relieve the acute suffering, warmth to the abdomen, and a prompt cathartic to cause its rapid expulsion, or six or eight calomel powders two or three hours apart, followed the next morning by a saline (R. Hydrarg. chlor. mit., gr. ½-½; sodii bicarb., gr. ij; pulv. ipecac., gr. ½; sacch. lact., gr. iij. M. ft. charta.).

Chronic variety. Of the first importance is the diet, which should be restricted in amount and confined almost entirely to articles which are readily digested in the stomach, such as beef, eggs and milk.

The hepatic, pancreatic and intestinal secretions should be stimulated by a course of alkalies, one of the most efficient being sodii

phosphas, 3j-ij, three times a day, or the following excellent combination:

R.	Sodii phosphat., .											
	Acid. phosph. dil.,											
	Syr. zingib.,	٠	۰	í	۰	۰	٠	۰	٠	. 3	· 131	M.
	Inf. gentian co.,		۰			۰		q.	. S.	aa	. 13 vj.	TAT .
-	0 17 011					C.			- 1 -			

Sig.—One tablespoonful in water after meals.

Aid intestinal digestion by the administration of R. Papoid, gr. j-ij; naphtalini, gr. j; ext. nucis vomicæ, gr. ½. M. Ft. pil. One such to be taken every four or six hours, or liquor pancreaticus, f3j-iv, or extractum pancreatis, gr. ij-vj, with sodii bicarbonatis, gr. v-x, two or three hours after meals, or fel bovis purificatum, gr. j-iij, after meals.

For constipation, bitter waters, such as Bedford, Friedrichshall, Pullna, or Hunyadi Jânos, or resina podophyllum, at bedtime.

INTESTINAL COLIC.

Synonyms. Enteralgia; tormina; gripes.

Definition. A spasmodic contraction of the muscular layer of the intestinal tube; characterized by acute paroxysmal pain near the umbilicus, relieved by pressure, and associated with feeble cardiac action.

Causes. Constipation; presence of indigestible food; collections of flatus; an abnormal amount of bile discharged into the intestines; lead poisoning; syphilis; chronic malaria; rheumatism; hysteria.

Symptoms. Romberg thus describes a paroxysm: "There are attacks of pain, spreading from the navel over the abdomen, alternating with intervals of ease. The pain is tearing, cutting, pressing, most frequently twitching, pinching, accompanied by peculiar bearing-down pains. The patient is restless, and seeks relief in changing his position and in compressing the abdomen; his surface may be cold and his features pinched. The pulse is small and hard. The abdomen is tense, whether puffed up or drawn inward. There are often nausea and vomiting, and desire for stool. There is usually constipation, but sometimes the bowels are regular or even too loose. Duration from a few minutes to several hours, relaxing at intervals. The attack ceases suddenly, with a feeling of the greatest relief, although some soreness remains for a few days."

Lead colic is always preceded by symptoms of lead poisoning, to

wit: slate-colored skin, dark gums showing a blue line, heavy breath, with sweetish metallic taste, obstinate constipation, impaired appetite, slow pulse and contracted abdominal walls.

Diagnosis. Gastralgia differs from colic, in the pain being in the epigastric region and associated with disorders of digestion.

In hepatic colic, or the passage of gallstones, the pain is in the hepatic region, attended with soreness over the gall bladder, and retching and vomiting, followed by jaundice and the presence of bile in the urine.

In *nephritic colic* the pain follows the course of one or both ureters, shooting to loins and thigh, with retraction of the testicle of the affected side, strangury and bloody urine.

In uterine colic the pain is in the pelvis, and associated with menstrual disorders, in fact, a dysmenorrhœa.

In ovarian colic or neuralgia, pain on pressure over the ovaries, with hysterical phenomena.

Inflammatory disorders of the abdomen differ from colic by the presence of fever and tenderness on pressure.

Prognosis. Most favorable. Death is the rarest termination possible.

Treatment. Relief of pain is the first indication, and is best accomplished by a hypodermic injection of *morphina*, gr. ½-½, which has the additional advantage of relaxing the spasm, thereby favoring the action of *purgatives*, which should soon follow. One of the best in colic, no matter from what cause, is *massæ hydrargyrum*, gr. v-x, or *hydrargyri chloridum mite*, gr. ½ every half hour until four or five grains are taken, followed by a mild *saline cathartic*.

After the relief of the pain and free action of the bowels, the cause of the attack should be ascertained and corrected, to prevent future suffering.

For *lead colic, morphina*, for the pain; *oleum ricini* or *magnesii sulphas*, 3j, every hour for the constipation, and *potassi iodidum*, gr. v-x, after meals, to eliminate the metal from the system. Excellent results often follow a free or several small venesections in lead poisoning.

Gratifying results in attacks of lead colic have been reported from tumblerful doses of *oleum olive*, repeated until some six ounces have been used. It is said to be curative in lead poisoning, in daily doses of two ounces, continued for some time.

CONSTIPATION.

Synonyms. Intestinal torpor; costiveness.

Definition. A functional inactivity of the intestinal canal, either due to atony of the muscular coat, causing lessened peristalsis, or to a deficiency of intestinal and biliary secretion; characterized by a change in the character, frequency and quantity of the stools.

Causes. Dyspepsia; character of the food; habits of the patient; diseases of the stomach and liver; malaria; lead poisoning; syphilis.

Symptoms. In the normal condition the majority of persons have *one stool* each day, although it is not to be considered abnormal if more or less than that number occur.

The bowels are moved every three or four days, with great straining and distress, the face often flushed, the cerebral vessels full.

Or in other cases the bowels may be relieved once a day, but the stool is small and hard, causing great distress.

Another group of cases have *frequent stools* during the day, *small* and *non-formed*, due to retained hardened fæces acting as an irritant upon the rectum.

The change in the character of the stools is soon followed by symptoms of dyspepsia, headache, mental torpor, vertigo, palpitation on exertion, and in many cases with great distention of the abdomen.

Prognosis. Death never results from functional constipation.

Treatment. The successful treatment depends upon the *removal* of the cause and the hearty co-operation of the patient.

First, the patient must have a regular hour each day for going to stool, and must remain a sufficient time to permit a thorough evacuation of the bowels.

Second, the diet must be carefully regulated.

Third, purgative mineral waters or cathartic medicines are to be used with caution, their reckless administration often doing more harm than good.

Fourth, either of the following formulæ, aided by the enforcement of the above rules, will give good results:—

В.	Ext. nucis vomicæ,					٠	gr. 1/4	
	Ext. belladonnæ alco.,					ı	gr. 1/4	
	Ext. aloes aqua.,						gr. ss	
	Pulv. rhei.,						gr. i	
	Olei cajuputi,						ott. i.	M
	* * *						S J.	674.0

In pill, at bedtime, and after a week, every second or third night.

Dx ·	Restrice podopnyr.,
	Ext. physostig.,
	Ext. belladonnæ alco.,
	Aloine, gr. 1/4
In p	ll, every night, or second or third night.

₽.	Ext.	cascar	æ s	sag	grada	e,	fld	٠,		۰				۰	mxx
		erini,													
	Syr.	sarsapa	aril	læ	, .	۰	۰			٠	٠	٠		۰	mxx.
Hou	r afte	r meals	s. c	r (once	a	da	v	as	in	die	at	ed.		

Success often follows an enema of glycerini 3j-iv, or a suppository of glycerinum.

Electricity to the abdomen is worthy a trial; one pole over abdomen the other at anus, using either galvanism or faradism.

DIARRHŒA.

Synonyms. Enterorrhæa; alvine flux; purging.

Definition. Frequent loose alvine evacuations, without tenesmus; due to functional or organic derangement of the small intestines, produced by causes acting either locally or constitutionally.

Causes. Those acting locally, such as indigestion, indigestible food, impure food and water, irritating matters or secretions poured into the bowels, or entozoa, cause the flux by a direct irritation of the mucous surface.

Attacks of diarrhœa due to constitutional derangement may be secondary to such diseases as tuberculosis, pyæmia, albuminuria, typhoid fever, or disturbances of the functions of other organs, giving rise to vicarious fluxes.

Atmospheric changes as well as a sudden mental shock will predispose to an attack of diarrhœa.

Forms. Acute and chronic.

Symptoms. Acute diarrhœa presents itself in several varieties, the result of its particular cause, to wit:—

Feculent diarrhæa. A few hours after meals the patient feels colicky pains and flatulency, with a desire for stool. There is often nausea, coated tongue, but seldom vomiting. The pain is generally relieved by the purging which ensues. The stools have a feculent character, are of brown fluid, containing fæces, often offensive, the

color becoming lighter after four or five evacuations. Constitutional symptoms are wanting.

This form is the result of over eating, eating too rapidly, or indigestion of different forms, or worms in the intestinal canal, and patients generally recover in a day or two.

Lienteric diarrhea. In this form there is, with the frequency of evacuations, a want of assimilation of food, which passes through the intestines more or less unaltered. The stools are frequent, mucous or serous, more or less covered with bile, mixed with undigested food. In this form the patients emaciate rapidly, owing to the deficient assimilation, the digested portions of the food being hurried on by the increased peristalsis of the irritated bowel. It is usually subacute in its course.

Bilious diarrhæa. The stools are frequent, green or yellow, with scalding sensations at the anus and griping pains in the abdomen. Excessive biliary secretion is the irritating cause.

Any of the above forms may pass into chronic diarrhea by exciting permanent diseases of the intestines. Diarrhea due to constitutional causes will be mentioned when speaking of those conditions.

Chronic diarrhwa results from repeated attacks of the acute form, or is the result of some cachexia. The symptoms, as far as the stools are concerned, are much the same as the acute disease, except they are paler, whence it has been termed white flux; in addition, dyspeptic symptoms, aphthous condition of the mouth and tongue, flatulency, colic, emaciation, and anæmia. The appetite is at times capricious, again impaired.

Prognosis. Favorable in *feculent* and *bilious* forms; unfavorable in *lienteric* and *chronic* forms when emaciation begins. Diarrhœa occurring as a symptom, the prognosis is controlled by the original disease.

Treatment. Acute diarrhæa. If the tongue is heavily coated, the breath fetid, and the stools not excessive in number, it is well to clear the intestinal canal with a laxative such as oleum ricini or a saline. For children between one and two years of age:—

R .	Pulv.	ipecac.,										gr. ½	
	Pulv.	rhei, .										gr. 1/4 - 1/2	
	Sodii	bicarb.,			٠							gr. ss-ij.	M.
Eve	r y four	hours u	ntil	the	cl	nara	acter	of	the	sto	ols	change.	

As a rule, however, the stools have become so frequent when ad-

vice is sought that the time for laxatives has passed, and some one of the following combinations is indicated:—

R .	Salol,								۰	۰	٠		gr. xxiv-xlviij	
	Bismuth subnit.,												Zi	
	Sacch. lac.,	۰	•	۰	٠	٠	۰	۰	۰	٠	۰	٠	3j.	M.
-														

Sig.—One every two or three hours, reducing the dose for children.

Or :--

R.	Bismuthi salicylat.,											gr.	xxx	
	Morphinæ sulph., . chart. No. vj.	٠	٠	٠	•	٠	٠	٠	٠	•	٠	gr.	j.	M.

Sig.—One every three hours.

Or the following modification of "Squibb's diarrhœa mixture:"-

₽.	Tinct. opii deodorat	t.,								f z viss	
	Tinct. camphoræ,		٠							fZi	
	Tinct. capsici, .								۰	fzv	
	Chloroformi purze,									f Z iiss	
	Spts. vini gallici,		۰							fZj	
	Alcoholis,	0		٠	. 1	ad	۰			fživ.	M.
C	0 , 63										

SIG.—One teaspoonful, p. r. n.

Or the following, which I have always found successful:-

Ŗ.	Tinct. opii deodorat.,					٠		٠			f 3 vss	
	Spts. chloroformi,		۰	۰				٠		۰	fāij	
	Acid. sulphuric. dil., .	٠		٠	٠	٠.	٠		۰	٠	f 3 j	
	Vini pepsini,					ad	q.	S.	٠	۰	f Ziv.	M.

Sig.—One teaspoonful in water after each stool.

For the bilious form :-

R.	Hydrargyri chlor.	mitis,							gr. ½	
	Sodii bicarb.,			۰	٠	۰			gr. ij	
	Pulv. opii,					a	0	۰	gr. ¼.	M.

In powder, every two or three hours, until eight powders are used, followed by large doses of bismuth and pepsinum.

In all acute forms restricted and regulated diet are imperative, pure milk with liquor calcis being the most suitable.

In adults, an *opium* suppository often checks a flux that is uninfluenced by opium internally.

In *lienteric* or dyspeptic diarrhœa a carefully regulated diet and either of the following combinations:—

D-naini almaani

	Dk -	repsini giycerit., .												
		Liq. potassii arseni	it.,								۰		m xxiv	
		Tinct. opii deodora	at.,		٥			۰				٠	fʒij	
		Aq. chloroformi .												M.
	Sig	—One teaspoonful	at r	ne	al	tin	ıe.							
r	_													
	R	Papoid,			٠				٠	٠	٠		gr. xxiv	
		Bismuth subnit., .												M.
	Ft	. chart. No. xij.												
	Sig	-One at meal time	.											

£ 7;

Chronic diarrhwa. Bismuth, gr. xxx-xl, in milk, every four hours; Hope's camphor mixture, $f\bar{g}$ every four hours, or cupri sulphas, gr. $\frac{1}{12}$, ext. opii, gr. $\frac{1}{12}$, every four hours, or argenti nitras, gr. $\frac{1}{2}$, ext. opii, gr. $\frac{1}{5}$, every five hours; may all be used with more or less success; when dry tongue and great flatulency, use:—

Ŗ.	Ol. terebinthini,						. fʒj
	Ol. amygdal., express.,						
	Tinct. opii,		۰	۰	۰		. fgij
	Mucil. acaciæ,						. f g v
	Aq. laurocerasi,						. f \(\frac{7}{3} \) ss. M.
SIG.	-fzi every three or four						

The diet should be nutritious in character, and moderate stimulants are indicated. Activity of the skin and kidneys should be encouraged.

All varieties of intestinal catarrh or diarrhœa are benefited by a few days rest in bed and daily hot baths.

CATARRHAL ENTERITIS.

Synonyms. Intestinal catarrh; acute diarrhœa; inflammation of the bowels.

Definition. A catarrhal inflammation of the mucous membrane of the small intestines; characterized by fever, pain, tenderness, and looseness of the bowels. When the catarrh is limited to the duodenum it is termed *duodenitis*.

Pathological Anatomy. There first ensues hyperæmia of the mucous membrane and intestinal glands, manifested by redness, swelling and ædema; this is followed by increased secretion, and an overgrowth and desquamation of the epithelium, together with a copi-

ous generation of young cells. As a result of the hyperæmia, rupture of the capillaries and extravasation of blood often occur.

The swollen glands show a strong tendency to ulcerate. This catarrhal process may involve the entire tube or be limited to portions of it. If the catarrhal changes extend to the *ileum*, the solitary and Peyerian glands show swellings that might be mistaken for the changes of typhoid fever.

Causes. A specific virus seems probable in some cases. Improper and indigestible food; summer temperature and exposure to cold and wet, while perspiring. Swallowing fish bones, cherry stones, unmasticated kernels of nuts, etc.

Symptoms. Begins with languar, followed by chilliness and fever, the temperature ranging at 102°-103°, this is followed by pain, colicky and paroxysmal in character, situated above the umbilicus, localized tenderness and loose evacuations. Nausea and vomiting often occur. The bowels are at first constipated, followed by persistent diarrhea; the stools contain but little fecal matter, are yellow or greenish-yellow in color, mixed with undigested food; if the stools are numerous, they become whitish and watery, the so-called "ricewater" discharges. No blood in stools. The appetite is impaired, and this, with the want of assimilation and great waste, soon produce extreme weakness and emaciation, which is always more marked in children. I have frequently noted a peculiar abdominal eruption in severe cases of intestinal catarrh, occurring as isolated dark red spots, larger than those of typhoid fever, lasting each, twenty-four hours, disappearing on pressure and with decline of fever.

Duration. In mild cases, four or five days; severe cases continue more or less marked, for a week or two.

Diagnosis. From *colic*, by the absence of tenderness and fever, and presence of constipation and its paroxysmal character.

From *typhoid fever*, by the absence of prodromes, characteristic step-like temperature record and characteristic eruption.

For points of distinction from dysentery or peritonitis, see those affections.

Prognosis. Favorable, if early and proper treatment is employed.

Treatment. Rest the bowels by a restricted diet, such as milk and lime water, or weak mutton or chicken soups, with well boiled rice added.

Keep the patient quiet in bed, a difficult matter in the case of children.

For adults, opium is the remedy, in doses to control the symptoms; mild cases do well with—

Or-

R. Tinct. opii deodorat., gtt. x Liq. potassii citrat.,
$$3\,ij$$
. M. Every hour until opium effect.

The strength and the frequency of administration of either of these formulæ must be governed by the severity of the attack.

Salol gr. j-iij, and bismuth salicylas gr. x-xv every few hours, is often of value in intestinal catarrh, although my experience is favorable to opium.

If vomiting is annoying, all other treatment must be discontinued until it has been controlled, the following being usually efficient (R hydrarygri chlor. mite, gr. ½; sodii bicarbon., gr. ij; sacch. lac. gr. ij. M. and give every hour or two, dry, on tongue).

For children:-

R.	Tinct. opii deodorat.,				۰				. gtt. j	
	Bismuth. subnit.,	٠	٠			٠			. gr. v	2.5
	Mist. cretæ,		a	٠	٠	a	۰	۰	. f3j.	M.

Every two hours, for a child of one year.

If the case shows the least tendency to linger the *acid* treatment should be substituted, one of the best formulæ being "Hope's Camphor Mixture." The following, which I have used with much success in the insane wards of the Philadelphia Hospital, where at times, we see a good deal of intestinal catarrh, and which I have named "Mistura Enterica," is generally satisfactory:—

R .	Spts. camphoræ, .									
	Acid. sulphurici,	all.	, ,						13188	
	Tinct. opii deodora	at.,				۰			fžj	
	Tinct. capsici									
	Spts. chloroformi,				٠	۰			f Z ss	
	Spts. vini gallici,				q.	S.	ad		f Z vi.	M.

Sig.—One to two teaspoonfuls well diluted, every three or four hours.

Locally. Poultices, warm fomentations, or ung. belladonnæ or oleum camphoratæ, give great relief.

CROUPOUS ENTERITIS.

Synonym. Membranous enteritis.

Definition. A croupous inflammation of the mucous membrane of the small intestines; characterized by tenderness, paroxysmal pain, moderate fever, and the formation and discharge at stool of membranous shreds or casts.

Causes. A disease of adult life. The female sex more liable than the male, and neuralgic, nervous, hysterical or hypochondriacal subjects are more subject to it than are other types.

A peculiar state of the nervous system seems necessary to its production. It is not a frequent disease.

Pathological Anatomy. A subacute inflammation of the small intestines, during which the mucous membrane becomes covered with a whitish or grayish-white, firmly adherent, membranous deposit, cemented together by a coagulable exudation, and prolonged by rootlets from its under surface into the intestinal follicles.

Symptoms. Begins by feverishness, feeling of soreness and distention of the abdomen; these are followed by pains of a colicky character, severe and depressing, felt around the umbilicus, associated with tenderness, continuing for half an hour, an hour or longer, and after a longer or shorter interval occurring again; these phenomena continue for a day or two, when looseness of the bowels, with distressing pain and tenesmus occur, the stools containing mucus, with or without blood, and shreds of membrane or cylindrical casts of the bowel. Great relief is then experienced, although a feeling of rawness or soreness persists for a day or two.

Preceding the local manifestations of the disease are attacks of hysteria, hypochondriasis, neuralgia, nervousness or excitability.

The paroxysms recur at intervals of a week or two, or after several months; as long an interval as three years between attacks is recorded.

Diagnosis. *Peritonitis* may be suspected until the characteristic stools occur.

Dysentery is excluded when the shreds and casts of membrane appear.

Prognosis. Favorable as to life, but one of the most difficult of diseases to eradicate.

Treatment. The *diet* must be such as contains but a minimum of fecal-forming matter.

For the pain and suffering, opium in some form is indicated, the most effective being a hypodermic injection of morphina.

For constipation during a paroxysm, an emulsion of oleum ricini and terebinthina is of benefit.

To prevent a return of the paroxysms either liquor potassii arsenitis, gtt. j-ij, before meals, or hydrargyri chloridum corrosivum, gt. 160, three times a day, with a course of oleum morrhuæ, seems to answer in the majority of cases. Prof. Da Costa speaks highly of pix liquida in some form, as an alterative to the mucous membrane.

Under no circumstances must the bowels become constipated.

CHOLERA MORBUS.

Synonyms. Sporadic cholera; English cholera; bilious cholera. Definition. An acute catarrhal inflammation of the mucous membrane of the stomach and intestines, of sudden onset; characterized by violent abdominal pains, incessant vomiting and purging, cold surface, rapid, feeble pulse, spasmodic contractions of the muscles of the abdomen and extremities, and prostration.

Causes. A disease of summer and early autumn, climatic influence being an important factor. Its prevalence during certain seasons seems to indicate a specific cause. Irritants of all kinds, unripe fruits and vegetables, and fermentation of food.

Pathological Anatomy. Cases in which death has occurred within a few hours present no pathological changes.

Generally, however, the gastro-intestinal mucous membrane is congested and denuded of epithelium; the solitary and Peyerian glands are swollen and prominent. The blood is thick, and dark in color; the kidneys are enlarged and congested; and in prolonged cases there are appearances of granular changes in the muscular system.

Symptoms. Onset sudden and violent, and unfortunately, generally after midnight, with chilliness, intense nausea, vomiting and purging, accompanied with distressing burning or tearing abdominal pains or colic. The vomited matter at first consists of the ordinary contents of the stomach, and the stools of ordinary faces, but soon the discharges by vomit and stool are liquid, whitish or of a green or yellowish tint; if the attack is severe or protracted the discharges are of the "rice-water" character. The patient is rapidly ema-

ciated and reduced in strength, the body shrinks, the surface cold and covered with a clanmy sweat, and the pulse is feeble. Intense thirst is present, and when drink is given it is at once rejected.

Aggravating the distress of the patient are servere cramps of the muscles, and especially those of the calves, and of the flexors of the thighs, forearms, fingers and toes.

Termination. Mild cases often terminate favorably without treatment, the patient able to be around in a day or two, although weak.

Severe cases, the vomiting and purging cease after some hours, but the patient remains weak, with irritable stomach and bowels for a week or two.

Grave cases, the true cholera type, recover from the prostration very gradually; reaction coming on slowly and usually passing into a typhoid condition of some weeks' duration.

Diagnosis. Asiatic cholera and cholera morbus are easily confounded during an epidemic of the former, and there are no positive points of discrimination, unless the *comma bacilli* of Koch are proven to be always in the true cholera stools.

Irritant poisons, such as tartar emetic, elaterium, or other substances, cause vomiting and purging, similar to cholera morbus, and are only discriminated from it by the clinical history and cause.

Prognosis. In the majority of cases favorable. The mortality is about five per cent.

Treatment. At once, regardless of the cause, a hypodermic injection of morphinæ sulph., gr. $\frac{1}{3}$, and atropinæ sulph., gr. $\frac{1}{120}$, to be repeated in half an hour if no improvement; for patients who object to the hypodermic mode, opium in some form by the mouth or rectum, giving the preference to the liquid preparations.

Camphora and opium combined often act well, or the "enteric mixture" mentioned on page 98, and if much depression, small doses of brandy or dry champagne.

The *intense thirst* must not be gratified by the use of liquids, but small *pellets of ice* by the stomach are grateful.

If the vomiting and purging continue, make use of-

₿.	Bismuth subnit.,								
	Acid. carbol., .						٠	gr. 16	
	Glycerini,							gtt. xx	
	Aquæ,							f 3 iv.	Μ.
-									

Every hour in water.

If the vomiting is so severe that no opportunity occurs for the medicament to come in contact with the gastric mucous membrane, an enema of *chloral*, gr. x-xv, in some demulcent with *tinctura opii deodorata*, mx-xx, acts often like magic in quieting the distress of the tortured patient.

The closer the case approaches the true cholera type, the more severe are the *muscular cramps*, and their treatment is indicated. Prof. Da Costa suggests—

R. Chloral,
$$3^{iv}$$
Cosmoline 3^{iv}
To be rubbed over the affected muscles.

Dr. Bartholow suggests-

Locally, *sinapis* in the form of poultices or the dry powder, should be applied to the abdomen, or *terebinthina* stupes, or the hot water bag.

The after treatment depends upon the symptoms; generally an acid mixture and a regulated diet, with tonic doses of quinina, are indicated.

ENTERO-COLITIS.

Synonyms. Inflammatory diarrhœa; ulcerative entero-colitis.

Definition. A catarrhal inflammation of the lower portion of the small—ileum—and the upper portion of the large intestines, with a great tendency to ulceration of the intestinal glands if the catarrh becomes chronic; characterized by moderate fever, nausea, vomiting, diarrhæa, swollen abdomen, pain and emaciation. A common disease of childhood.

Causes. Improper and indigestible food; summer temperature; impure air; uncleanliness; exposure to cold and damp air.

Most commonly a disease of childhood.

Forms. Acute and chronic.

Pathological Anatomy. Acute variety; hyperæmia, swelling, cedema and softening of the mucous membrane of the lower portion

of the small and the upper portion of the large intestines, with hyperplasia of the intestinal follicles, their excretory follicles enlarged and tumid, readily distinguished as grayish or blackish points in the middle of the glands; the patches of Peyer are also enlarged, tumefied, and project above the level of the surrounding mucous membrane, the orifices of the follicles appearing as dark points; these patches often have an ulcerated appearance, but upon close examination such is found not to be the case.

Chronic variety; the thickening and infiltration have extended to the submucous and muscular coats, followed by induration of the tissues, so that the walls of the intestines are often abnormally rigid. Ulceration occurs, which extends through the entire thickness of the membrane. "These ulcers, when isolated, are from one to one and a half lines in diameter, oval or circular in shape, and either have sharp-cut edges, as though the piece of mucous membrane had been cut out with a punch, or the mucous membrane bounding them is undermined." The small ulcers often coalesce, so that large, irregular ulcerated patches are formed, having for their base the submucous or muscular coats, and have a grayish-white color.

The mesenteric glands are enlarged, but seldom, if ever, undergo ulceration.

Symptoms. Acute form; may develop slowly, with restlessness and fretfulness, or suddenly with feverishness, loss of appetite, thirst, nausea, moderate vomiting, and abdominal pain; or diarrhwa may be the first indication of illness on the part of the child. Regardless of the character of the onset, the stools soon present the characteristic appearance; they are semi-fluid, heterogeneous, greenish, acid, mixed with yellowish fragments of ordinary fæces, and undigested casein, termed the "chopped spinach" stools. The abdomen is enlarged and tender.

Emaciation is marked in proportion to the severity of the symptoms; in marked cases the child is reduced to a condition of the greatest debility within a very few days.

Chronic form, or ulcerative entero-colitis, usually follows the acute form, the character of the symptoms being less severe, but decidedly persistent, the strength fails, the temper is very irritable, the complexion grows dark, sallow and unhealthy, the skin dry and harsh, and in consequence of the marked emaciation, either hangs in folds around the shrunken limbs, or is drawn tightly over the joints; the

abdomen is enlarged and tender, the stools numbering from six to a dozen during the day and night, consisting of the products of an imperfect digestion mixed with mucus, serum, pus, and oftentimes blood, having a semi-fluid consistency, and an extremely offensive odor. Ulcerative stomatitis is a frequent complication adding to the discomfort of the patient.

Duration. Acute form, from ten days to about two weeks, subsiding gradually; chronic form, from one to two or three months, or even longer.

Diagnosis. The acute form can hardly be mistaken for any other condition, if the characteristic stools and other abdominal symptoms are present. The chronic form has been frequently mistaken for the diarrhea of tuberculosis, an error that can hardly occur if a physical examination of the chest has been made.

Prognosis. Always a very serious malady, and proves fatal if it attacks the weak during midsummer, or when surrounded by unfavorable hygienic conditions; in vigorous children, who have passed through their first dentition, the prognosis is quite favorable.

Treatment. For the *acute form*, restricting the amount of food for the first few days is of importance. Fresh, pure air, cleanliness and rest are also of great importance.

Any one of the following formulæ may be used with advantage:-

Sig.—Such a powder every two hours.

Or-

₽.	Hydrargyri chlor.	mi	ite,	,		۰		۰	۰				gr. ½	
	Pulv. ipecac.,		٠	۰		0			ø			۰	gr. ½	
	Pulv. opii,	۰	۰	٠	0	٠	٠	٠	٠	۰			gr. ½	2.6
Ft	Cretæ præparat., chart. No. xij.	٠		٠	٠	۰	٥	۰		٠	۰	٠	gr. xxiv.	M.

Sig.—One every two or three hours, to child of one year.

Many cases do well with *pulvis kino comp.*, others with minute doses, frequently repeated, of *acidum lacticum*, and many others with *bismuth*, gr. x-xv, in milk, every few hours, to quite young children.

Locally, warmth to the abdomen, with mustard, turpentine stupes or the spice poultice, made as follows: cloves, allspice, cinnamon, and anise seeds, each half an ounce, pounded (not powdered) in a mortar,

and placed between two pieces of coarse flannel about six inches square and quilted in; soak this for a few minutes in hot brandy or hot whisky and water, equal parts, and apply to the abdomen, heating again as it becomes cool.

Chronic entero-colitis. Few conditions will tax the skill and patience of the physician to the same degree as will this variety.

First and foremost the diet must be carefully regulated. Milk alone, or predigested, or with lime-water, in the majority of cases is the best article of diet. Should it disagree, then recourse must be had to some of the prepared foods, such as Mellin's, Horlick's, Ridge's, Blair's prepared wheat, and many others; often the one agreeing with one patient will not agree with another.

After caring for the diet, then the hygiene of the patient requires attention. Cleanliness, such as daily warm-baths, often adding with advantage sea-salt. Rest in bed for an hour or more after meals if the patient cannot be kept continually in bed. The air of the room should be fresh and pure.

Amongst drugs may be mentioned bismuth and pepsinum or Salicinum.

CHOLERA INFANTUM.

Synonyms. Choleriform diarrhæa; summer complaint.

Definition. An acute catarrhal inflammation of the mucous membrane of the stomach and intestines, together with an irritation of the sympathetic nervous system, occurring in children during their first dentition; characterized by severe colicky pains, vomiting, purging, febrile reaction, and prostration.

Cause. Age; bad hygiene, or as it is now entitled, "civic malaria;" continuous high temperature; improper food; dentition; constitutional as in the feeble, delicate, nervous, or irritable.

Pathological Anatomy. Resembles closely, if not identical with, the phenomena of catarrhal gastritis and enteritis, together with a powerful irritation of the fibres of the sympathetic system.

Symptoms. The onset is *sudden* in a child previously well, or in a child suffering from a bowel affection.

Begins with vomiting, purging, abdominal pain, fever, rapid pulse and intense thirst.

The *vomited matter* is partly digested food, sero-mucus, and finally bilious, and is accompanied with distressing *retching*. The *thirst* is a marked phenomenon of the disease, and ice and water will be taken incessantly, although rejected only a few moments after.

The *stools* are first partly fecal, but soon watery or serous, soaking the clothing, leaving a faint greenish or yellowish stain; their odor is musty, at times fetid; their number is from ten to twenty in the day.

Pains precede the vomiting and purging, colicky in character.

The fever begins at once, the temperature varying from 101° to 105°, with morning remissions. The pulse is rapid and feeble, ranging from 130 to 160.

These symptoms continue but a few hours, before rapid wasting ensues, the body shrinks, the eyes are sunken and partly closed, the mouth partly open, the lips, dry, cracked and bleeding. The child, at first irritable and restless, passes into a semi-comatose condition, the pulse becoming more and more feeble, the surface has a clammy coldness, the contracted pupils not responding to light, and the stupor deepens, death soon following, or the symptoms slowly ameliorate, convalescence being slow and tedious.

Diagnosis. The entero-colitis or inflammatory diarrhœa of child-

hood is constantly being mistaken for cholera infantum. The symptoms of the former are, gradual onset, with fretfulness, loss of appetite, feverishness, nausea, and moderate vomiting, soon followed by diarrhæa, the stools being semi-fluid, greenish, mixed with yellowish particles of fæces and undigested casein, with a sour odor, the "chopped spinach" stools, the abdonen distended and tender, moderate fever and thirst, and having a duration of about two weeks.

Prognosis. Difficult to predict the result, and so care must be used in giving a prognosis. The duration of the choleraic symptoms is short, under five days, but relapses are common, and the sequelæ are protracted.

Treatment. Change of air of the greatest benefit. Restricted diet, and particularly for first few days, using *brandy*, gtt. v-x, in *barley water* at frequent intervals.

For the *vomiting*, large doses of *bismuth*; or *chloral*, gr. j-iij, by mouth in demulcent, or double the amount by the rectum, or one of the following:

R .	Bismuthi subnit.,												Зij.	
	Acid. carbolici, .							٠					gr. j	
	Mist. acaciæ,	۰					,							
	Aq. menth. p., .													M.
SIG.	-Teaspoonful ever	v]	hal	f l	10	ur.	ho	oui	r. (or	tw	0	hours.	

Or-

hours

Good results are reported from *bismuthi salicylas*, gr. ij, with sugar of milk every hour or two, or *salol* gr. i-ij every two or four

Cases that have resisted other remedies have rapidly improved under the following:—

R.	Tinct. verat. alb.,											. fgij	
	Morphinæ acetat.,									٠		. gr. ij	
	Spts. vini gallici,	۰	٠	۰	٠				-	٠	٠	. f Z ij.	М.
Et a	dde zj to												
	Aquæ calcis,												
	Aquæ menthæ, .	۰		٠		āā						. f 3 j.	M.
SIG	-One teaspoonful,	re	pe	ate	d	ev	ery	h	ou	r,	if	needed.	

If the fever is high, sponging with alcohol and water, the cold pack or the cool bath can be used first, and afterwards using stimulants.

For *depression*, regulated nursing or feeding every two hours, and water or ice to quench the intense thirst, and *cognac brandy*, gtt. v-x, every hour or two, in water, by mouth or in warm enema.

Locally; over epigastrium, mustard or a spice poultice, or turpentine stupes.

If the *nervous symptoms* become aggravated, small dose of *potassii* bromidum, or valerian, which "reduces the reflex excitability, motility and sensibility," is indicated.

ACUTE DYSENTERY.

Synonyms. Colitis; ulcerative colitis; bloody flux.

Definition. An acute inflammation of the mucous membrane of the large intestines, either catarrhal or croupous in character, followed in some cases with ulceration, characterized by fever, tormina, tenesmus and frequent, small, mucous and bloody stools.

It occurs either sporadically, endemically or epidemically.

Four clinical forms are described: acute catarrhal; amœbic or tropical; croupous or diphtheritic; chronic dysentery.

Causes. Sporadic, endemic or catarrhal dysentery, prevails most extensively in the summer and early autumn months. Sudden atmospheric changes, such as hot days and cool nights. Malaria has some connection with its causation. Errors in diet not a cause. The drinking water may be the means by which the poison gains entrance to the system.

Amæbic or tropical dysentery, characterized by the presence in the stools of the amæba coli (Lösch) or Amæba dysenterica (Councilman and Lafleur). This variety is often epidemic in the tropics.

Croupous or diphtheritic dysentery is often epidemic; frequently occurs as a terminal event in acute and chronic diseases. The causes are much those of the acute catarrhal form, acting upon a depressed system. The Amæba coli may be seen in the stools.

Dysentery is not contagious, but is infectious.

Pathological Anatomy. Catarrhal dysentery; congestion, swelling and cedema of the mucous membrane and sub-mucous tissue of the large bowel, with an over-production of mucus; the fol-

licles are enlarged, from retention of their contents, the result of the swelling; the congested vessels often rupture; the mucous membrane softens in patches, and is detached, forming ulcers. Recovery follows, if the destruction of tissue is small, smooth cicatrices, minus gland stricture, marking the site.

Amæbic or tropical dysentery, the lesions are also in large intestines and sometimes in lower portion of the ileum. Abscess of the liver is a common complication.

"The lesions consist of ulceration, produced by preceding infiltration, general or local, of the submucosa, the general infiltration being due to an ædematous condition, the local to multiplication of the fixed cells of the tissue. In the earliest stages these local infiltrations appear as hemispherical elevations above the general level of the mucosa. The mucous membrane over these soon becomes necrotic and is cast off, exposing the infiltrated submucous tissue as a grayish-yellow gelatinous mass, which at first forms the floor of the ulcer, but is subsequently cast off as a slough." (Osler.)

Croupous or diphtheritic dysentery begins with intense congestion, swelling, and cedema of the mucous and sub-mucous tissue, with extravasations of blood and the whole mucous membrane covered with a firm, fibrinous exudation; the mucous membrane softens and sloughs, leaving large ulcers and gangrenous spots. If recovery occur, large cicatrices form, which narrow the calibre of the intestinal tube.

The mesenteric glands enlarge, soften, and abscesses form in them; the liver becomes the seat of small abscesses, from embolic obstruction of the radicles of the portal vein; the heart muscles are flabby and more or less fatty.

Symptoms. Catarrhal form begins gradually, with diarrhaa, loss of appetite, nausea, and very slight fever, which continues for two or three days, when the true dysenteric symptoms develop, to wit, pain on pressure along the transverse and descending colon, tormina or colicky pains about the umbilicus, burning pain in the rectum, with the sensation of the presence of a foreign body and a constant desire to expel it, or tenesmus; the stools for the first day or two contain more or less fecal matter, but they soon change to a grayish, tough, transparent mucus, containing more or less blood and pus; during the tormina, nausea and vomiting may occur; the urine is

scanty and high colored; the number of stools vary from five to twenty or more in the twenty-four hours.

The duration is about one week, the patient being much emaciated and enfeebled.

Anabic form begins gradually as the catarrhal form, or gradually as an increasing diarrhæa. Soon the stools become characteristic of the variety of the attack, being frequent, bloody, mucoid, but very fluid; as the disease progresses the stools become yellowish-gray and liquid, containing mucus, sometimes bloody. The number of stools varies from six to a dozen or more in a day. Actively moving anæbæ are found in the stools, disappearing as the stools become formed. Fever may or may not be present, or may come and go. Abdominal pain and tenesmus are present in the majority of cases.

The loss of flesh and strength is marked. Abscess of liver and lungs are frequent and grave complications.

Duration from six to twelve weeks, recovery tedious owing to anæmia and loss of flesh.

In every endemic or epidemic of dysentery a number of amæbic cases will occur. During the past three years I have seen probably two hundred cases of dysentery, beginning as catarrhal, but in the midst of the endemic a number of amæbic cases occurred, the convalesence long outlasting the catarrhal variety.

The croupous or diphtheritic form sets in suddenly, the stools being more frequent, containing more blood and pus, with patches of membrane, even casts of the bowel, together with more or less gangrenous mucous membrane; nausea, vomiting, and great prostration, cold skin, feeble pulse and emaciation with anxious expression, the odor surrounding the patient being fetid.

The occurrence of this form as a termination of Bright's disease, lung and heart disease, must be borne in mind.

The duration of the grave symptoms is three or four days, when collapse and death occur, or slow convalescence begins, continuing for weeks.

Chronic Dysentery. This is really a continuation of the acute disease, the symptoms continuing the result of the ulcerated mucous membrane, or the cystic degeneration of the glandular elements of the large gut (Woodward). Rarely, dysentery develops subacutely, and thus is almost chronic from the beginning. There is seldom a

characteristic stool, little colicky pain and little or no tenesmus, but a progressive loss of flesh with loose bowels, the stools containing mucus, little or no blood, undigested food, and are frothy. The number varies from two to a dozen in the day. Acute exacerbations are frequent. Duration, often months or years.

Complications. Peritonitis; hepatic abscesses; phlebitis of the intestinal veins; intestinal perforation.

Diagnosis. Enteritis lacks the tenesmus and characteristic stools. Peritonitis, when idiopathic, shows higher temperature, greater tenderness and constipation.

Chronic dysentery is difficult to distinguish from chronic diarrhæa. **Prognosis.** Catarrhal form favorable, save in those debilitated.

Amæbic form; the mortality is higher than in catarrhal form, and in favorable cases the convalescence is slow.

Croupous form; the prognosis is always grave, for, if recovery does occur, the bowels may be crippled from loss of structure, or from narrowing of its calibre, the results of cicatrices.

Treatment. Keeping in mind the following from Osler's Practice, no case of dysentery, however mild, should be lightly considered: "Dysentery is one of the four great epidemic diseases of the world. In the tropics it destroys more lives than cholera, and it has been more fatal to armies than powder and shot."

The patient should be confined to bed in even the mildest attack, and the stools removed at once and *disinfected*. In fact, the bed-pan or other vessels should constantly contain a solution of *ferrous sul-phate* (copperas) sufficient to cover the expected stool.

The diet to be of the most nourishing yet bland character, adding stimulants if much prostration.

The most frequently used drug, and in many cases by far the best, is opium, alone or combined with one or more astringents:—

R.	Ext. opii, Plumbi acetat.,							gr. ss gr. ij.	M.
	v two hours.								

Or-

Ŗ.	Pulv. opii,							gr. ss	
	Plumbi acetat.,							gr. ij	
	Pulv. ipecac., .							gr. ¼.	M.
Distan	m toma hanna								

Every two hours.

I have frequently seen the character of the stools change within twenty-four hours with the *Mistura enterica*, viz.:—

₿.	Acid. sulph. dil., .						٠				f 3 iss	
	Tinct. opii deodorat.,						۰				fžj	
	Spts. camphoræ, .								٠		f℥j	
	Tinct. capsici,		4			٠		۰			f 3 ss	
	Spts. chloroformi, .			4						۰	f $\frac{7}{3}$ ss	
	Spts. vini gallici, .	0			٠	0	۰				f ξ iss.	M.

Sig.—One teaspoonful every two or three hours, diluted.

In more than one instance I have seen a severe attack of acute dysentery succumb to *morphina sulphas*, gr. $\frac{1}{2}-\frac{1}{2}$, three or four times daily hypodermically, within three or four days. For the intense tormina and tenesmus no remedy is comparable with morphia by the hypodermic method.

If the case is seen early, the very best prescription possible is-

Magnesii sulph., .											
Acid. sulph. dil., .	0	٠	٠	٠	٠				٠	Μx	
Tinct. opii deodorat.,							n		۰	mχ	
Aquæ chloroformi	,						. :	ad.		3 ij	Μ.

Every two or three hours, until fæces appear in the stools, when small doses of opium and quinina may be used.

Bismuth subnit., gr. xxx, every two or three hours, or bismuth salicylas, gr. xv, every two or three hours, are often successful.

Dr. Loomis speaks strongly of *ipecacuanha*, gr., ½ every half hour, with sufficient opium to secure quietness. The large doses of ipecacuanha recommended I have had no experience with.

Ringer recommends hydrargyri chloridum corrosivum, gr. $\frac{1}{100}$, every hour or two, which "rarely fails to free the stools from blood and slime, although in some cases a diarrhœa of a different character may continue for a short time longer."

In children the following combination is efficacious:-

R .	Pulv. ipecacuanhæ,					٠		٠			gr. ¼	
	Bismuth subnit.,	٠	۰	٠		٠			۰	۰	gr. v-x	2.5
	Cretæ præp.,	۰	۰	٠	٠	٠	٠	٠		۰	gr. 11J.	M.
SIG.	Every two hours.											

Washing out the rectum with either tepid, hot, cold or iced water, as suggested by Prof. DaCosta, adds greatly to the patient's comfort and to the decrease of the inflammatory process. Ice suppositories are often soothing.

A one or two per cent. solution of *creolin* (one-half pint) as an enema often rapidly lessens the number of stools and the tenesmus. Dr. H. C. Wood recommends iodoform suppositories.

"In the cases of amœbic dysentery we have been using at the Johns Hopkins' hospital, with great benefit, warm injections of quinine in strength of 1 to 5000, 1 to 2500, and 1 to 1000. The amæba are rapidly destroyed by it." (Osler.)

Locally, poultices, stupes, etc., do no good, but if they are agreeable to the patient, they may be allowed, as they do no harm.

Chronic dysentery. A carefully selected but nourishing diet, change of scene and some of the following remedies: Bismuth, gr. xxx, t. d.; terebinthina, $m_i x_i$, every three or four hours; argenti nitras, gr. $\frac{1}{16} - \frac{1}{16}$, three or four times daily; or $m_i x_i$. Cupri sulphas, gr. $\frac{1}{16}$; ext. opii aq. gr. $\frac{1}{16}$ - $\frac{1}{16}$; ext. nucis vomicae, gr. $\frac{1}{16}$, in pill, four times daily.

Chronic dysentery is sometimes kept up by a trifling patch of inflammation or ulceration in the rectum or sigmoid flexure. There occur two or three loose stools in the morning, and then a comparatively comfortable day. The stools are preceded by some colicky pain across the lower part of the abdomen and in the line of the large bowel. The general condition, other than the anæmia and weakness, of the patient is good. Drugs by the mouth are useless to control these cases; the medication must be made directly to the diseased part. Injections of argenti nitras, gr. iv to xx or xxx to the pint are curative; the silver may be combined with opium (R. Argent. nitrat, gr. j; tinct. opii deodorat., mxv-xx; aquæ amyli, f3iv, M).

During the convalescence from all varieties of dysentery, tonics are indicated; (R. Strychninæ sulph., gr. 1/3; acid. hydrochlorici dil., f3ij; tinct. gentian comp. q. s., ad f3iv, M. S.—One teaspoonful before meals in water). A course of oleum morrhuæ with syr. calcii lactophosphatis, should be used if much emaciation.

TYPHLITIS.

Synonyms. Inflammation of the cæcum; typhlitis stercoralis. Definition. A catarrhal inflammation of the mucous membrane of the cæcum and ascending colon; characterized by pain, tenderness, constipation, and in certain cases a characteristic vomiting.

Causes. In a majority of cases mechanical, due to the accumulation of fæces in the cæcum.

Pathological Anatomy. Similar to the catarrhal inflammation of dysentery.

Symptoms. Pain and tenderness in the right iliac fossa and along the ascending colon, with some prominence of this region; the bowels are distended with gas (meteorism) and are usually constipated, or small liquid stools may occur from time to time, due to the accumulation of hardened faces in the sacculated periphery of the cacum, leaving a central canal through which the liquid contents of the upper bowel can pass.

In severe cases, "the local pain, tenderness and swelling are greater, there are impaction of faces and no movements. There are decided fever, restlessness and also nausea and vomiting. The vomited matters, at first the contents of the stomach, then the duodenum, with bilious matter, and ultimately, if the impaction persists, of material having the odor of faces. With these symptoms occur great depression of the vital powers. Peritonitis is finally developed by contiguity of tissue or by rupture of the bowel."

The *temperature* in even mild cases is one or two degrees above the normal and in a fair majority of cases an *eruption* is seen upon the abdomen, consisting of one or two dark red spots the size of a pinhead, which are of short life and disappear on pressure.

Duration. The *mild form* form lasts about one week. The *severe* form may terminate in subacute peritonitis, continuing about two weeks.

Diagnosis. The *mild form* is distinguished from other intestinal affections by the localized pain, tenderness and prominence, and the constinution.

The severe form can only be distinguished from the other forms of intestinal obstruction by the history of the case and attack, and the results of treatment.

Prognosis. Mild form favorable. Severe form grave, although not necessarily fatal.

Treatment. The patient should be kept in bed, and placed on a strictly milk diet in very limited amounts for a few days.

Two indications are to be met, which are seemingly opposed to each other: first, the removal of the accumulation of fæces, which in the majority of cases has caused and still maintains the inflammation; second, to retard the inflammation resulting from the presence of the fecal mass.

If the pain and suffering be intense, at once administer a hypodermic injection of *morphia*.

The two indications above named are met by the use of the following:—

If it be true that calomel has a specific action upon the lower portion of the small bowel, increasing the secretion from the glands located there, then the following should be useful in some cases:—

SIG.—One every hour till twelve taken, followed by f 3 iv hot Hunyadi-Janos water.

In severe cases, begin an opium influence at once, by hypodermic injections of morphina guarded with atropina, continued until all symptoms of inflammation have subsided, when attempts to remove the accumulated fæces may be made by irrigation of the bowel with warm soapsuds, and the cautious administration of magnesii sulphas in drachm doses, every two hours.

Locally, hot, dry applications, or the ice bag.

PERITYPHLITIS.—APPENDICITIS.

Synonyms. Perityphlitic abscess; suppurative appendicitis; pericæcal abscess.

Definition. *Perityphlitis*; an acute inflammation of the connective tissue around the cæcum (with localized peritonitis) leading to the formation of an abscess.

Appendicitis. An acute or sub-acute inflammation of the appendix vermiformis, involving the surrounding tissues (with a localized

peritonitis) leading to perforation of the appendix and the development of an abscess.

Causes. The great majority of cases of perityphlitis are secondary to inflammation of or perforation of the vermiform appendix—appendicitis. Have seen two cases of true perityphlitis the result of exposure to cold and wet.

Appendicitis usually results from the presence of a foreign body in its canal, consisting of inspissated fæcal masses, which, becoming incrusted with lime salts, are termed "fæcal calculi," and becoming rounded in shape closely resemble a cherry-stone, for which they have been mistaken. Foreign bodies, particularly seeds of fruit, sometimes, but not so often as is believed by the laity, gain access to the appendix and produce inflammation leading to perforation. Torsion of the appendix is also among the infrequent causes. The disease is more common in males than females. Occurs most frequently between the ages of ten years and thirty years. Relapses are fairly frequent in cases not progressing to perforation.

Symptoms. The symptoms of the two conditions are much alike; begins with a feeling of weight, soreness and rapidly developing and severe pain in the lower right abdomen, accompanied with nausea and vomiting. The pain is increased by lying on the left side, the right leg is drawn, the abdomen becomes tense, prominent and tender, with the progressive development of a hard swelling in the right iliac region. The temperature at the onset is from 99°-100°, and may or may not be preceded by a chill; the pulse 80, full and strong; the tongue coated with red tips, the bowels costive. In addition to the persistent, localized pain, occurs severe colicky paroxysms, which may shoot into the hip and thigh. The expression of the patient is pinched and denotes suffering. The special tendency of the disease is toward suppuration, which is announced by irregular chills, feverishness, the temperature shooting suddenly to 101°-103°, and sweats, and a feeling of tension and throbbing. Its development is slow, and if associated with typhlitis the symptoms of that affection are added.

Complications. Perforation of the appendix. Local or general peritonitis.

Diagnosis. Differs from *typhlitis* by the absence of the colicky pains, dyspeptic symptoms, costive bowels and tympanites preceding

the development of a tumor; in perityphlitis the tumor is present with the development of the symptoms.

Psoas abscess is not associated with intestinal symptoms, and the discharge is free from a fecal odor. Renal and ovarian tumors should not be sources of error. The possibility of hernial tumors must not be overlooked.

Treatment. If not associated with typhlitis, the treatment is to allay the inflammation in the first stage, by either *ice*, *locally*, or freely painting with tinctura iodi; if suppuration is evident, hasten by hot applications, and follow by evacuation of the pus with the aspirator or a free opening, conjoined with the use of opium and quinina.

If the disease is not rapidly controlled, a laparotomy with strict

antiseptic precautions is indicated.

PROCTITIS.

Synonyms. Catarrh of the rectum; dysentery; rectitis.

Definition. A catarrhal inflammation of the mucous membrane of the rectum and anus; characterized by pain, tenesmus and frequent stools of hardened fæces, or of mucus, pus and blood.

Causes. Chief cause constipation; also sitting on damp ground or stone steps; habitual use of enemata or of purgatives; diseases of the liver: hemorrhoids.

Pathological Anatomy. Similar to those occurring in catar-

rhal dysentery.

Symptoms. Uneasy sensation and burning in the rectum, with a constant desire for stool, or tenesmus, often so severe as to cause a prolapse of the mucous membrane. The stools may be either hardened faces or scybala from the distended colon, which cause intense pain when they reach the rectum; or the stools may be of mucus, muco-pus or bloody or blood-streaked. Generally there are present nausea, especially during the tenesmus, headache, feverishness and malaise. In severe cases there is strangury, and with the tenesmus, straining with urination.

If the case be protracted and severe, inflammation of the connective tissue around the rectum occurs, causing *periproctitis*, which usually terminates in various kinds of fistulæ.

Complications. Periproctitis; peritonitis; hepatic abscesses.

Diagnosis. In *males*, the disease cannot be confounded with any other affection, save, perhaps, hemorrhoids. In *females*, displacements of the uterus may somewhat simulate the symptoms of proctitis.

Prognosis. Uncomplicated cases favorable. Either of the complications adds greatly to the gravity of the affection.

Treatment. In cases due to constipation the chief indication is to empty the bowels, using an enema of warm water and soap or magnesii sulphas (R. Magnesii sulph., 3ij; glycerini, 3ss; aquæbul., f3iv. M.). Irrigation of the bowel with warm water once or twice daily assists in the liquefaction of the hardened fæces. Either enemata or suppositories of glycerinum should answer in certain cases.

Cases other than those due to constipation, emollient enemata and opium, one of the best being—

The use of *hot injections* of an astringent character, such as hot, strong black coffee, from half pint to quart, as hot as will be tolerated by the rectum, as suggested by Dr. Pepper, is valuable in cases of irritable rectum with a disposition to looseness. In cases not benefitted by the hot injections, relief may follow the use of injections of water, say two ounces, as cold as can be borne without chilling; administered at bedtime, having it retained.

If symptoms of *periproctitis* occur, use *ice* to the parts, and if suppuration ensue, *evacuation* by a free opening and *quinina*.

INTESTINAL OBSTRUCTION.

Synonyms. Intestinal occlusion; strangulated hernia; invagination; intestinal stricture; ileus.

Definition. A sudden or gradual closure of the intestinal canal; characterized by pain, nausea, vomiting, constipation, and finally collapse.

Causes. The numerous causes are arranged as follows:-

- 1. Accumulations within the bowel, of hardened fæces, or foreign bodies.
 - 2. Strictures, the result of cancer, ulceration, or cicatrices.

- 3. Pressure against the bowel, from peritoneal adhesions, tumors, and abnormal growths.
 - 4. Strangulations, due to the numerous forms of hernia.
 - 5. Invagination or intusussception, the most common.
 - 6. Twisting, volvulus or rotation of the bowel.

Pathological Anatomy. Invagination is the form calling for special description here. It is usually caused by the lower portion of the ileum slipping down into the cæcum, as the finger of a glove might be invaginated, causing thus an actual mechanical obstruction; this is produced by a spasm of the ileum, whereby its calibre is greatly diminished, thus permitting its descent into the lower bowel. Resulting from this occlusion or compression, are congestion, inflammation, with secondary constitutional reaction and death, or more rarely the invaginated bowel sloughs off, and is voided by stool, union taking place at its site and recovery following.

Symptoms. The onset of the symptoms may be either sudden or gradual, and are as follows:—

Constipation, with more or less severe colicky pains, not relieved by either purgatives or injections; feeling of weight and soreness, with distention of the abdomen and nausea and vomiting; the symptoms all grow more pronounced, the pain becoming violent, tenderness in limited areas, the vomiting becoming stercoraceous, the abdomen hard and tense, the eyes sunken, the pulse quick and feeble, the skin cold, and covered with a clammy sweat. The above continue more or less pronounced for a week or ten days, when collapse and death occur, or more rarely there is a gradual return to health.

Cases occur rarely in which small, fecal, muco-purulent stools containing more or less blood exist, instead of constipation.

Diagnosis. One of the most difficult, and can only be solved by a careful study of the case along with the different causes producing the affection. The site of the occlusion can rarely be determined positively.

Intestinal obstruction may be mistaken for intestinal colic, hernia, enteritis, peritonitis, hepatic or renal colic.

Prognosis. Always grave, but guided by the cause. *Impacted faces* favorable. *Invagination* less favorable, but recoveries occur; the longer the symptoms continue, the more favorable the outlook. *Strangulations* unfavorable, but many recoveries recorded. *Strict*-

ures, due to cancer, cicatrized ulcers and the like, are the most unfavorable.

Treatment. Stop all forms of purgatives as soon as the diagnosis of obstruction is determined.

Opium is indicated in all forms with pain, and is best administered in the form of *morphina*, combined with small doses of *atropina*, hypodermically.

The author has seen the most brilliant results follow the plan of washing out the stomach as suggested by Küssmaul, and with full doses of atropina hypodermically, for its action on intestinal peristalsis, and with electricity, one pole over abdomen, the other in rectum.

Cases resulting from *impacted* faces are rapidly cured by the above plan combined with *irrigation* of the lower bowels with tepid soapsuds.

If invagination, raising the buttocks and lowering the chest, and repeated injections of warmed oil, are recommended.

Distention of the bowel by pumping air through long rectal tubes, or disengaging carbonic acid gas in the bowel, by first injecting a solution of sodii bicarbonas, and follow this with a solution of acidum tartaricum, about one drachm of each, pressure being made against the anus to prevent escape; but the danger of rupture of the bowel must not be overlooked.

Flatulent distention can be removed by the long aspirator needle.

Laparotomy is no doubt the operation of the future, when our means of diagnosticating the location of the trouble is more exact.

The *nutrition* of the patient is best attained by injections of either peptonized foods or defibrinated blood, or both.

INTESTINAL PARASITES.

TAPEWORMS.

Varieties. Tania solium; Tania saginata; Bothriocephalus latus.

Causes. The *Tænia solium*, the "armed tapeworm," is the most common in this country. It is derived from the embryos contained in *pork*, known as the *cysticercus cellulosus*.

The Tania saginata, the "unarmed tapeworm," a not uncommon variety, is derived from the embryos contained in beef, known as cysticercus bovis.

The Bothriocephalus latus, also an "unarmed tapeworm," the largest parasite infesting man, is supposed to be derived from an embryo found in fish.

The embryo or ovum is introduced into the intestinal canal with the food and drink. The parasite reaches its final growth after its entrance into the intestines.

Those handling fresh meats or eating uncooked animal food are most liable to be affected.

Uncleanliness is also an important factor.

Description. The tania solium is from six to thirty feet in length, has a globular head, or scolex, a slender neck connecting its numerous flat segments or joints. The head, or scolex, measures about $\frac{1}{40}$ of an inch, has a double circle of hooklets,—whence the term "armed tapeworm,"—and is provided with from two to four suckers. The segments or joints (strobila) are flat, and vary from one-eighth to one-half an inch in length, and each contain both male and female sexual organs, the uterus being a long, numerously branched tube, in which the ova develop; the ova measure about $\frac{1}{1700}$ of an inch in diameter. An ordinary tapeworm contains some five million ova.

The parasite is firmly imbedded in the mucous membrane of the upper third of the small intestines by its hooklets and suckers.

The lower or terminal segments represent the adult and complete animal, and are termed the *proglottides*, which separate from the parasite and are discharged either alone or with the feces.

The tania saginata is from ten to forty feet in length, has a

rounded or oval-shaped head, measures about $\frac{1}{10}$ of an inch and has four strong and prominent suckers, but no hooklets,—whence the term "unarmed tapeworm;" the neck is short and thick and the *segments* are larger, stronger and thicker than those of the T. solium.

The *Bothriocephalus latus* is the largest of the three Cestoda, the length ranging from fifteen to sixty feet, the head oval, measuring about $\frac{1}{10}$ of an inch, a short neck, the segments or joints being nearly three times as broad as they are long. Its color is a dull, bluish-gray. Zoölogically considered, this variety is not a true tapeworm.

Symptoms. Not unfrequently a *tænia* produces no symptoms whatever.

Usually, however, there are colicky pains throughout the abdomen, inordinate appetite, disorders of digestion, emaciation, constipation, attacks of cardiac palpitation, faintness, disorders of the special senses and pruritus of the anus and nose. Any or all of these symptoms may be present.

A large meal will often remove the majority of the symptoms present.

In a large number of cases the discovery of the *segments* is the first intimation of the presence of the parasite.

Treatment. A number of remedies—termed tæniafuges—are used more or less successfully for the expulsion of the tapeworm, to wit: extractum granati rad. cort. fluidum, f 3ss-ij, or a decoctum granati rad. cort. (3ij bark of root, aquæ Oj), wineglassful every hour until all is taken, as suggested by Prof. Bartholow; or oleoresina aspidii, 3ss doses repeated, or oleum pepo express., f3j-iv, followed by oleum ricini. Creosotum has been successful in a number of cases. Several cures are reported from glycerinum f3ij-3j, repeated p.r.n.

A much pleasanter remedy is *pelletierine*, the active constituent of *granatum*, used in the form of the *tannate*, gr. x-xx, or *Tanret's solution of pelletierine*.

Cases which resist these means are often cured by the following:-

R. Chloroformi,
Ext. aspidii fid.,
Emul. olei ricini, f ʒ i ij.

M.

Sig.—To be taken in the early morning; no food until after thorough action of the bowels.

An important precaution in the management is close attention to the "preparatory treatment" rendered essential to remove the mucus in which the *head* (scolex) is imbedded. It consists in the administration of a thorough purgative for one or two days, and a light diet, such as milk and broths, preceding the use of the tæniafuge.

ROUND WORMS.

Varieties. Ascaris lumbricoides; Oxyuris vermicularis.

Causes. The ascaris lumbricoides is one of the most common of the parasites affecting the human family, and develops in the intestines, either after the entrance of the ova of the same, or from the so-called "intermediate parasites." Their entrance is effected by means of the food and drink.

The oxyuris vermicularis develops in the large intestines, from either its peculiar ova, or the so-called "intermediate parasite," these finding their way into the bowel with the food and drink, or by direct contact.

Description. The ascaris lumbricoides, or the round worm, is of a brown color, a cylindrical body, from ten to twenty inches in length, and from an eighth to a fourth of an inch in circumference; the head terminates in three semilunar lips, each having about two hundred teeth. The ova are oval-shaped, are produced in immense numbers, some sixty million in a mature female, have wonderful vitality, resisting extreme heat or cold.

The round worm inhabits principally the small intestines, although it often migrates to other parts. They are found in numbers from one to several hundred.

The oxyuris vermicularis, thread or seat worm, resembles an ordinary piece of white thread, measuring from a sixth to a half inch in length, the head terminating in a mouth with three lips, the tail terminating as a sharp point. The ova are oval, produced in large numbers, each female containing about ten thousand, and are surrounded by a stout envelope, which increases their vitality.

The seat worm, as its name indicates, inhabits the large intestines, especially the rectum, although they frequently migrate to the sexual organs. They vary in number, sometimes the parts frequented being entirely covered.

Symptoms. The ascaris lumbricoides, or round worm, may be

present in great numbers and yet produce no characteristic symptoms other than gastric and intestinal irritation, such as picking the nose, foul breath, colicky pains, nausea and vomiting, diarrhœa and disturbed sleep, such as tossing from side to side of bed and grinding the teeth. Any or all of these symptoms may be present or absent; a positive diagnosis may be based upon the passage of the parasite.

The oxyuris vermicularis, or seat worm, produces intense itching about the anus, with a desire for stool, the passages often containing much mucus, the result of the irritation produced by their presence. Should they migrate to the sexual organs, intense itching of these parts results, which, unless speedily corrected, leads in children to masturbation.

Treatment. The ascaris lumbricoides are readily removed by the following "worm powder:"—

Sig.—At bedtime, followed by a dose of oleum ricini before breakfast.

For the oxyuris vermicularis the above santoninum powder, with the use of enemata of quassia, alumen, sodii chloridum, or R., acidi carbolici, gr. v-x, aquæ, Oj, according to the age, the injection not to be retained; or an enema of a weak solution of corrosive sublimate (1 to 10,000). Always precede any of the medicated enemata by a large injection of water to unload and clear the rectum. Washing the anus and external genitals with a solution of acidum carbolicum should also be employed. For the pruritus ani apply a little unguentum hydrargyri.

DISEASES OF THE PERITONEUM.

PERITONITIS.

Synonym. Inflammation of the peritoneum.

Definition. A fibrinous inflammation of the peritoneum, either acute or chronic, characterized by fever, intense pain, tenderness, tympanites, vomiting and prostration. It may be limited to a

part, local, or it may involve the entire membrane, general, peri-

Causes. Acute variety: Intense cold; protracted irritation by blisters; blows upon the abdomen; penetrating wounds of the abdomen; inflammation or perforation of the stomach, intestines, gall or urinary bladder, vermiform appendix or the surrounding parts; inflammation of the pelvic viscera; septicæmia or pyæmia; erysipelas; hernia.

Many surgeons doubt that peritonitis is ever an idiopathic disease, but that rarely it does so occur is certain.

Chronic variety: Tuberculosis; albuminuria; scrofula; cancer; sclerosis of the liver.

Pathological Anatomy. Acute form: hyperæmia of the serous membrane, the capillaries distended and occasional extravasations of blood from their rupture; the normal secretion is arrested, and the shiny membrane becomes dull and opaque, from an exudation of pure fibrin, which is adhesive, gluing the parts together; if the inflammatory action is now arrested, it is termed adhesive peritonitis; if, however, the action progress, an effusion of serous fluid is poured out into the peritoneal cavity, the amount varying from a few ounces to several gallons; this is termed exudative peritonitis. If recovery result, the fluid is absorbed, with much of the solid exudation, the unabsorbed portions forming adhesions between the membrane and the different abdominal organs, often causing great deformity and irregularity in their relations.

Local or circumscribed peritonitis is the same as general except that adhesions develop around the site of attack so rapidly that the inflammatory action is encapsulated. Why this occurs in some cases and not in others is not known. Pus develops if the absorption is not prompt or if any cachexia be present.

The chronic form follows the acute, or is associated with tuberculosis, scrofula, Bright's disease or sclerosis of the liver.

The membrane is irregularly thickened and opaque, with strong adhesions to one or more coils of the intestine, the liver or spleen; the quantity of fluid present is small, purulent or sero-purulent in character, and encysted by the agglutinated membrane.

Symptoms. Acute form; when idiopathic, the onset is sudden, with a chill, fever, 102-3°, pulse 100-140, wiry and tense, severe pain, cutting or boring in character, and tenderness, becoming so great

that the slightest touch aggravates it, the *decubitus* being on the back with flexed thighs; the *abdomen* is *distended* and *rigid*, from *constipation*, *effusion* and *meteorism*; the diaphragm is pushed up as far as the third or fourth rib in severe cases, causing compression of the lungs, and displacement of the heart, liver and spleen. There is *impaired appetite*, and *nausea* and *vomiting* are almost constant, as is *hiccough*. It is a clinical fact that a sub-normal temperature is of frequent occurrence in acute peritonitis.

Secondary form, from extension, begins with local and gradually increasing pain, the temperature increases, tense pulse and vomiting. If from perforation, it is announced by severe pain and all the symptoms of shock.

Purulent peritonitis, usually secondary (most commonly seen in those with chronic Bright's disease), is accompanied with hectic phenomena

These symptoms continue from six to eight days, when they begin to decline and a tedious convalescence ensues, or pain and tenderness grow more marked, strength fails, surface cold, pulse rapid, and collapse, with hippocratic face, anxious expression, pinched features, sunken eyes, and drawn upper lip.

Chronic form, usually of tubercular origin, though other causes are given, shows irregular chills, fever and sweats, distended abdomen, constipation alternating with diarrhwa, diffused tenderness, with points of intenseness and hardness; colicky pains during digestion, rapid emaciation and failure of strength. Usually the lower portions of the abdomen give a dull note on percussion, from the presence of fluid, or scattered points of dullness, showing the presence of encysted fluid.

Diagnosis. The question of diagnosis in peritonitis is of great importance, as it is so frequently, if not always, associated with the diseases and accidents of the abdomen.

Acute gastritis differs from peritonitis in having a history of corrosive poisoning, severe pain, limited to the stomach, with early and severe vomiting; while the latter has fever, diffused abdominal pain and tenderness, with decided distention.

Acute enteritis has localized pain and tenderness with marked diarrhœa; constipation being the rule in peritonitis.

Rheumatism of the abdominal muscles occurs with a rheumatic history, is subacute, lacks the great abdominal distention and suffer-

ing expression of peritonitis, and while tenderness exists, it is not aggravated by deeper pressure.

Biliary colic, or the passage of a gall-stone, has, as a prominent symptom, excruciating pain, localized over the common bile duct, which is of a paroxysmal character and followed by slight passing jaundice. In renal colic the acute pain follows the course of the ureters, with retracted testicle and altered urinary secretion.

Prognosis. *Idiopathic cases* favorable, and especially if they continue longer than a week, as fatal cases usually end during the first week. Cases from perforation unfavorable.

Chronic peritonitis being generally of tuberculous origin, the prognosis is unfavorable, although partial or complete recovery results in the cases following the acute form of the disease.

Treatment. The peritoneal membrane being of such vast extent its general inflammation is one of the most formidable diseases the physician meets.

Acute form: Idiopathic and robust cases, locally, leeches or wet cups, followed by cold or hot applications, as most agreeable to the patient, or covering the abdomen with a blister; adynamic cases, dry cups, followed by warm applications medicated with tinctura opii.

The profession are divided between two plans of treatment for peritonitis, one side favoring *opium* and the other party as strongly urging saline purgatives and laparotomy.

Prof. DaCosta says opium and quinina are the remedies indicated at the onset of the disease, to wit: at once hypodermic of morphina, gr. ½-½, maintaining the effect by hourly doses of either morphina or opium, by the mouth. Prof. Clark ascertained the tolerance of opium in this disease, by the tremendous amounts used in a case under his care; the first day he gave 200 grs., the second day 472 grs., the third day 236 grs., fourth day 120 grs., fifth day 54 grs., sixth day 22 grs., and on the seventh day 8 grains. Prof. Clark found that, as a rule, however, morphina, gr. ½-½, every two hours, would maintain the effects of the drug. The opium should be guarded with sufficient doses of atropina. Quinina, gr. v, every four hours until exudation, after which gr. ij, four times a day, is of marked benefit.

While the opium treatment places the patient as well as the bowels "in splints" and relieves the pain, it is urged by the advocates of saline purgatives, however, that instead of locking up the bowels, the use of salines puts the bowels into active peristaltic action, whereby

the peritoneal cavity is drained of the products of inflammation and the inflamed surfaces are relieved of all engorgement by a thorough depletion of the vessels in the intestinal walls, the pulse and temperature are improved, the pain is lessened as quickly as by opium, and the formation of adhesions and bands is prevented.

Should the active symptoms continue under either plan of treatment, *laparotomy* is indicated.

The decline of the vital powers must be averted by regulated nutrition and free stimulation.

Locally, an ointment of belladonna and hydrargyrum is of value. During convalescence, perfect quiet, nourishing diet, moderate stimulation, scattered flying blisters, and the following:—

В.	Potassii iodidi, .								
	Ferri pyrophos., .							gr. ij	
	Elix. simpl.,							f 3 ss	
	Aquæ destillatæ,				ad			f z ij.	M.
Ever	y six hours,								

should constitute the treatment, with tonic doses of quinina.

Peritonitis from *perforation*, absolute quiet, hypodermic injections of *morphina*, ice locally, and stimulants per mouth, rectum, or hypodermically, and laparotomy.

For puerperal and other varieties of peritonitis following disease of ovaries, tubes, uterus, and laparotomy, the reader is referred to works on obstetrics and surgery.

Chronic peritonitis; locally tinctura iodi, and internally opium, for pain; potassii iodidum as an absorbent, with nourishing diet, oleum morrhuæ and stimulants, and rest in bed.

ASCITES.

Synonyms. Dropsy of the abdomen; peritoneal dropsy; hydroperitoneum.

Definition. A collection of serous fluid in the abdomen, or more correctly in the peritoneal cavity; characterized by a distended abdomen, fluctuation, dullness on percussion, displacement of viscera, embarrassed respiration, plus the symptoms of its cause.

Causes. Ascites may form part of a general dropsy, to wit: car-

diac or nephritic. The most common factor in its production is a *mechanical obstruction* of the portal system from cirrhosis of the liver, pressure of tumors, diseases of the heart or lungs.

Pathological Anatomy. The quantity of fluid in the peritoneal sac varies from a few ounces to many gallons. It is generally of a straw color, or at times greenish, and is transparent, having an alkaline reaction. When blood is present in any great quantity, it points to cancer as a cause. The peritoneum becomes cloudy, sodden, and thickened, from long contact with the fluid.

Symptoms. The onset is insidious, and considerable swelling of the abdomen occurs before the disease attracts attention. Constipation, from pressure of the fluid on the sigmoid flexure. Scanty urine, from pressure on the renal vessels. Embarrassed respiration and cardiac action, from displacement of the diaphragm upward. The umbilicus is forced outward.

Physical signs; on palpation, a peculiar wave-like impulse is imparted to the hand laying on the side of the abdomen, while gently tapping the opposite side.

Percussion; patient erect, the fluid distends the lower abdominal region, with dullness over the site of the fluid and a tympanitic note above; if the patient turns on his side the fluid changes, and dullness over the fluid, tympanitic note over the intestines.

Diagnosis. Ovarian tumors differ from ascites in the history, in that the enlargement is limited to the iliac fossa, instead of a uniform abdominal enlargement, not changing its position when the patient changes posture, and by the detection of a tumor by conjoined manipulation through vagina, or by rectal exploration.

Pregnancy differs from ascites in the character of the enlargement, the history, absence of menses, increase of mammæ, change in the neck of the uterus, absence of fluctuation, and the presence of the sounds of the fœtal heart.

Distention of the bladder has been mistaken for ascites; the points of distinction are, in the former the history, presence of tenderness over the bladder, rounded outline of the percussion dullness, and the relief afforded by the catheter.

Chronic peritonitis is differentiated by the history, pain, tenderness, more or less vomiting, thickened abdominal walls, and its generally being associated with tubercle or cancer.

Chronic tympanites presents the enlarged abdomen, but lacks the

history, the dullness and the fluctuation, giving instead a tense abdomen and a universal tympanitic note.

Prognosis. Influenced by the causes producing it. *Idiopathic ascites*, which is most rare, terminates in health within a few weeks. If *peritoncal*, generally favorable. If from *organic disease*, most unfavorable, for while the dropsy may be removed, it as rapidly returns.

Treatment. The first indication is to treat the cause of the ascites, and the second to remove the fluid.

Three modes of removing the fluid present themselves: *first*, by hydragogue cathartics; *second*, diuretics and diaphoretics, and *third*, tapping. The first and second modes may be combined, as follows:—

Or instead use the following:-

R. Hydrargyri chlor. mitis, gr. iij

Ext. opii, gr. \(\frac{1}{12}\).

Et ft. pil.

SIG.—One every three or four hours.

If these fail, as they certainly will after a time, the embarrassed respiration and cardiac action will call for *tapping*, which may be done with the *trocar*, or, better still, the *aspirator*. The tapping does not remove the cause, and the fluid often rapidly accumulates again. Before tapping always examine the bladder, using the catheter if there be any doubt.

As all modes of treatment weaken the patient, the diet should be highly nutritious.

DISEASES OF THE BILIARY PASSAGES.

CATARRHAL JAUNDICE.

Synonyms. Catarrh of the bile ducts; icterus.

Definition. An acute catarrhal inflammation of the mucous membrane of the bile ducts and of the duodenum; characterized by gastro-intestinal derangement, yellowness, itching of the skin, feverishness, and mental depression.

Causes. Excesses in eating and drinking; a debauch; malaria; climatic, as cool nights succeeding warm days.

Pathological Anatomy. The mucous membrane of one or more of the bile ducts, or of the duodenum, becomes hyperæmic, swollen and thickened, from an effusion of serum into the submucous tissue; the result of this condition is the closure of the biliary passages, thereby impeding the outward flow of bile. The bile in the hepatic ducts being retained by the obstruction, the result is a staining of the liver substance and an absorption of bile, and its appearance in the blood.

Symptoms. Begins by epigastric distress, coated tongue, impaired appetite, nausea, with perhaps vomiting, and looseness of the bowels and slight feverishness, the phenomena of a gastro-intestinal catarrh. In from three to five days the eyes become yellow, and jaundice gradually appears over the whole body; the feverishness disappears, the skin becomes harsh, dry and itchy, the bowels constipated, the stools whitish or clay-colored, accompanied with much flatus and colicky pains; the urine heavy and dark, loaded with urates and containing biliary elements.

A few drops of the urine placed on a whitish surface, and a drop or two of nitric acid made to flow against it, will exhibit the following "play of colors:" a greenish tint, from the conversion of bilirubin into biliverdin, quickly followed by blue, violet, red, and yellow, or brown.

When the jaundice is complete, the surface is cold, the heart's action slow, the mind torpid and greatly depressed, and pain or tenderness on pressure over the hepatic region.

Duration. In from three to five days after the jaundice appears

the symptoms subside, save the torpid bowels, depression and discolored skin, which slowly disappear, often requiring a week or two.

Diagnosis. There are two varieties of jaundice, and in arriving at a diagnosis this must be remembered. There is *hepatogenous*, obstructive or catarrhal jaundice, and *hematogenous*, non-obstructive or blood-change jaundice.

The numerous diseases, of which jaundice is a symptom, will be differentiated when treating of them.

Prognosis. Always favorable; if the attacks are of frequent occurrence, however, they are apt to lead to organic hepatic changes.

Treatment. Rest in bed, with a carefully regulated diet, avoiding all starchy, fatty, or saccharine articles, milk being the most suitable, adding lime water if stomach irritable.

The jaundice being the result of an acute catarrh of the duodenum and the ductus choledochus communis, treatment is to be directed to this condition by such remedies as sodii phosphas 3j, well diluted every four hours, or calomel and soda (R. Hydrargyri chloridi mitis., gr. ¼; sodii bicarbonatis, gr. iij; sacc. lac., gr. iij. M. Sig.—Taken dry on tongue every two or three hours until one dozen are used, followed by Hunyadi Janos water), or the following:—

В.	Sodii bicarb.,					. 3 ij
	Tinct. nucis vom.,				 	. f3iv
	Tinct. capsici,				 	fzi
	Tinct. rhei,					
	Inf. gent. comp. a					
STC	Dessertspoonful e					0 ,

M.

SIG.—Dessertspoonful every four or five hours, in water.

For the dry, itchy skin *diaphoresis* is indicated. The warm or hot bath night and morning is valuable, adding *potassii carbonas*, 3j to each.

If the urine continues scanty diuretics should be used, a simple and efficacious one being potassii bitartras lemonade at very frequent intervals. Spiritus ætheris nitrosi, m x-xx, diluted, is always valuable for torpid kidneys.

A special plan, which is said to be effective, is with "enemata of cold water. By means of an irrigating apparatus the large intestine is well distended with water once a day for several days. The first enema has a temperature of 60° F., and subsequent injections are a little warmer. The increased peristalsis of the bowels and the reflex contractions of the gall bladder dislodges the mucus obstructing

the gall ducts. When the bile flows into the intestine, digestion is resumed and the catarrhal inflammation subsides." Other remedies may be conjoined with the irrigation method.

BILIARY CALCULI.

Synonyms. Hepatic calculi; gall-stones; hepatic colic.

Definition. Concretions originating in the gall-bladder, or biliary ducts, derived partly or entirely from the constituents of the bile. Their presence is generally unrecognized until one or more attempt to pass along the ducts, when an attack of *hepatic colic* is produced.

Causes. Gall-stones result from the *precipitation* of the crystallizable *cholesterine*, and its combination with inspissated mucus in the gall bladder or ducts.

A disease of middle life, and more frequent in the obese, and in women.

Gall stones are said to be common in carcinoma of the stomach or liver.

Pathological Anatomy. Choiesterine is the chief constituent of biliary calculi. Commonly several stones exist, and rarely one; as many as six hundred are recorded. They are generally found in the gall-bladder or cystic duct, rarely in the liver or hepatic duct.

Symptoms. The presence of gall-stones or biliary calculi is made known only by their expulsion from the gall bladder, whence is developed hepatic colic.

Hepatic colic begins suddenly, at the moment a gall-stone passes from the gall-bladder into the cystic duct.

The patient is seized with a piercing, agonizing pain in the region of the gall-bladder, and spreading over the abdomen, right chest and shoulder; the abdominal muscles are cramped and tender; there is nausea and vomiting, a small, feeble pulse, cool skin, pale, distorted, anxious face, with, may be, fainting, spasmodic trembling, chills, or convulsions.

The paroxysm continues from an hour or two to several days, with

remissions, but entire relief is not afforded until the stone reaches the duodenum, when the pain suddenly ceases.

Jaundice usually follows the paroxysm of pain. When the calculi reach the intestines, the pain, nausea and vomiting cease, the appetite returns, and the jaundice soon disappears.

Should the calculi become impacted, *ulcerative perforation* and consequent *peritoritis* follow, the calculi discharging by the intestine, stomach, or through the abdominal walls.

Diagnosis. The malady should not be mistaken if severe pain, diverging from the hepatic region, and nausea and vomiting are present, suddenly terminating, and followed by slight jaundice. The diagnosis is always made positive by diluting the stools voided for the day following an attack of suspected hepatic colic, and passing them through a sieve.

Prognosis. Usual termination is in health. The prognosis becoming more unfavorable if ulcerative perforation result.

Treatment. For the *colic*, hypodermic injections of *morphina*, gr. $\frac{1}{20}$, combined with *atropina*, gr. $\frac{1}{20}$, and warm fomentations over the hepatic region, are indicated. *Oleum olivæ*, f $\frac{1}{2}$ ij-iv, every hour or two sometimes does good.

Prof. Bartholow strongly urges the following prophylactic treatment: Carefully regulated diet, abstinence from all fatty and saccharine substances, daily exercise, stoppage of all excesses, and the long use of sodii phosphas, 3j, before meals, well diluted, to which may be added, if gastro-intestinal catarrh be present, sodii arsenias, gr. $\frac{1}{20}$, or aurii et sodii chloridum, gr. $\frac{1}{20}$, together with either Vichy or Saratoga Vichy water.

DISEASES OF THE LIVER.

CONGESTION OF THE LIVER.

Synonyms. Torpid liver; biliousness.

Definition. An abnormal fullness of the vessels of the liver, with consequent enlargement of that organ; it is termed active when arterial; passive when venous. The condition is characterized

by torpidity of the digestive and mental functions, and slight jaundice.

Causes. Active congestion; heat, atmospherical or artificial; habitual constipation; malaria; excesses in eating and drinking; alcoholic or malt liquors. In females, an arrested menstrual epoch may give rise to an attack.

Passive congestion; cardiac and pulmonary diseases.

Pathological Anatomy. The liver is enlarged in all directions, and is abnormally full of blood. Cases due to obstructive diseases of the heart or lungs present the so-called "nutmeg liver," to wit: "At the centre of each lobule the dilated radicle of the hepatic vein, enlarged and congested, may be discerned, while the neighboring parts of the lobule are pale," the radicles of the portal vein containing less blood.

Long-continued congestion establishes atrophic degeneration of the organ; the decrease in size is confounded with the condition of cirrhosis, but the "atrophic liver" is smooth, while the "cirrhotic liver" is nodulated.

Symptoms. Active congestion; following cause, rapidly produced malaise, aching of limbs, evening feverishness, headache, depression of spirits, yellowish tongue, disgust for food, nausea, and, may be, vomiting, constipation, scanty, high-colored urine, with a feeling of fullness, weight, and soreness in the hepatic region, with dull pain extending to the right shoulder, and slight jaundice, the eye yellow, and the complexion muddy. Duration about a week.

Passive congestion; onset gradual, with a feeling of weight and fullness in the hepatic region, slight jaundice, and symptoms of gastro-intestinal catarrh.

On percussion the hepatic dullness is increased in all directions.

Diagnosis. Acute congestion is continually confounded with *catarrhal jaundice*; the latter begins with marked gastro-intestinal symptoms and distinct jaundice; in the former these are less marked.

Obstructive congestion is diagnosticated by the clinical history.

Atrophic or nutmeg liver will be differentiated from cirrhotic liver when speaking of the latter.

Prognosis. Active congestion favorable, unless repeated attacks occur, rapidly succeeding each other, when "atrophic degeneration" results.

Fassive congestion controlled entirely by the cause.

Treatment. Attacks due to excesses in eating and drinking-

R .	Sodii bicarb.,			,					gr. v
	Pulv. ipecac,		3		a			٠	gr. ss.
	Hydrargyri chlor.	mit.,				0			gr. 111-V,

repeated, or sodii phosphas, 3j, every four hours until free catharsis, or small doses of hydrargyri chloridum mite, with sodii bicarbonas repeated several times, followed with saline, followed by

R. Acidi nitro-hydrochlorici dil., m x.

Elix. taraxaci comp., f z ij.

Before meals, and a milk diet.

Attacks due to malaria; the above purgatives followed by quinina sulph., gr. iv. every four hours.

Attacks occurring with cardiac or pulmonary diseases must be managed by treating the cause.

The tendency to constipation must be overcome by the saline laxauve waters, to wit: Congress or Hathorn, Hunyadi Janos, or sodni phosphas, 3j-ij, three or four times daily, well diluted.

Locally, in acute attacks, hot cloths or sinapisms are of benefit.

In chronic cases benefit follows, elix. quinina, ferri et strychnina, f3j, three times a day, and great comfort and support is given by the use of the "hydropathic belt," which is made of stout muslin, shaped to the abdomen, with cross pieces of tape on the inner side, which keeps next to the skin a fold of cloth wrung out of cold water, and a piece of waterproof cloth or oiled silk, to prevent evaporation.

In persons who seem to have a predisposition to attacks of congestion of the liver upon the slightest exposure to any of the various exciting causes, the habits and diet must be regulated, to which must be added a course of alkaline waters and regulated exercise.

ABSCESS OF THE LIVER.

Synonyms. Parenchymatous hepatitis; acute hepatitis; suppurative hepatitis.

Definition. A diffused or circumscribed inflammation of the hepatic cells, resulting in suppuration, the abscesses being sometimes single, at times double; characterized by irregular 'febrile attacks,

hepatic tenderness, and symptoms of deranged gastro-intestinal and hepatic functions.

Causes. The result of the absorption of putrid material by the portal radicles in dysentery; ulcers of the stomach; malaria; blows and injuries; heat; pyæmia.

Pathological Anatomy. Hyperæmia, swelling, effusion of lymph, degeneration and softening of the hepatic cells; suppuration, beginning in points in the lobules and coalescing. The abscess walls consist of the liver structure, more or less changed.

The abscess may advance toward the surface of the liver, bursting into the peritoneum, intestines, stomach, gall bladder, hepatic duct or vein, or into the pleura or lungs, or externally through the abdominal walls; after the discharge of pus, cicatrization occurs, or the pus may be absorbed, the tissues around forming a dense cicatrix.

Symptoms. Very obscure. Fever simulating markedly intermittent or remittent fevers; disorders of the gastro-intestinal canal, with obstinate vomiting, debility, and great irritability of the nervous system, melancholia, slight jaundice, constipation, the stools light colored, and if of long duration, typhoid symptoms.

Locally, if the abscess is near the surface, prominence of the hepatic region, throbbing, limited tenderness, and if it tends to the surface, redness, cedema and fluctuation. The abscess may burst into the intestines, stomach, lungs, or pleura, the symptoms of which will be pronounced.

Diagnosis. Hepatic abscess may be confounded with hydatids of the liver, hepatic or gastric cancer, abscess of the abdominal walls, and purulent effusion in the right pleural cavity.

The differentiation is most difficult, but great aid is obtained from the use of the aspirator.

Prognosis. Unfavorable. Recoveries, however, do occur. If the abscess bursts into the lungs, bowels, or externally through the abdominal wall, the case is more favorable.

Treatment. Symptomatic, and when pus is present, the use of the aspirator to remove it, and sustaining treatment, quinina, ferrum, alcohol and oleum morrhuæ.

ACUTE YELLOW ATROPHY.

Synonyms. General parenchymatous hepatitis; malignant jaundice; hemorrhagic icterus.

Definition. An acute, diffused or general inflammation of the hepatic cells, resulting in their complete disintegration; characterized by diminution in the size of the liver, deep jaundice, and profound disturbance of the nervous system; terminating in death, usually, within one week.

Causes. Unsettled. It occurs frequently in young pregnant women, from the third to the sixth month of pregnancy. Other causes are venereal excesses, syphilis, action of phosphorus, arsenic or antimony.

Pathological Anatomy. Begins with hyperæmia of the hepatic cells, with a grayish exudation between the lobules, followed by softening, dull yellow color, and disappearance of the cells, fat globules taking their place; the liver is reduced in size and weight; the peritoneum covering the liver is thrown into folds; the spleen is enlarged; the kidneys undergo degeneration; the blood contains a large amount of urea and considerable leucin; the urine is loaded with bile pigment, and contains albumin.

Symptoms. *Prodromic period*; begins as a *gastro-intestinal catarrh*, coated tongue, nausea, vomiting, tenderness over the epigastrium, headache, quickened pulse, slight fever and slight *jaundice*.

Icteric period; jaundice deepens, pulse slow, headache increases, and persistent insonnia.

Toxamic period; fever, rapid pulse, more complete jaundice, pain, nausea, vomiting of blackish, grumous blood, or "coffee grounds," tarry stools, ecchymotic patches, convulsions or epileptiform attacks, coma, insensibility, death.

Percussion shows markedly decreased hepatic dullness.

Duration. Short. After appearance of jaundice, about six days. Prognosis. Unfavorable.

Treatment. Entirely symptomatic. Prof. Bartholow "advises the trial of very small doses of phosphorus, as early as possible, as this remedy affects the organ specifically, and an action of antagonism may be discovered between them."

SCLEROSIS OF THE LIVER.

Synonyms. Interstitial hepatitis; cirrhosis of the liver; hob-nailed liver; gin-drinkers' liver.

Definition. An inflammation of the intervening connective tissue of the liver, chronic in its progress, resulting in an induration or hardening of the organ, and an atrophy of the secreting cells; characterized by gastro-intestinal catarrh, emaciation, slight jaundice, and ascites.

Causes. The prolonged use of alcoholic stimulants, gin, whisky, beer, or porter; syphilis.

Pathological Anatomy. First stage; hyperæmia of the connective tissue (Glisson's capsule) of the liver, and the development of brownish-red connective-tissue elements, whereby the organ is increased in size and density; this increase of the connective tissue presses upon the hepatic cells, causing them to undergo fatty degeneration.

Second Stage; the newly formed, imperfectly developed connective tissue contracts, causing decrease in the size and induration of the organ, its surface being nodulated. The hepatic and portal circulation is obstructed, from obliteration of their radicles.

The hepatic peritoneum is thickened and opaque, and adhesions are formed to the diaphragm, gall-bladder, and stomach.

Cases occur in which the sclerosis takes place while the organ continues enlarged; these cases are known as hypertrophic sclerosis.

Symptoms. No characteristic symptoms of the early stage of the affection. Persistent gastro-intestinal catarrh, with attacks of jaundice, in a drinking man, are suspicious. Symptoms of the second stage are, abdominal dropsy, enlargement of the superficial abdominal veins, dyspepsia, localized peritoneal pain, hemorrhages from the stomach or intestines, muddy or slightly jaundiced skin and decided emaciation; the enormously distended abdomen with thin legs are characteristic of sclerosis of the liver.

Diagnosis. Atrophy of the liver, or the nutmeg liver, is almost always confounded with sclerosis; the former occurs most commonly with obstructive diseases of the heart and lungs, and the surface of the organ is not nodulated, nor is there a history of alcoholism.

Cancer and tubercle of the peritoneum have many symptoms akin to sclerosis. The points of differentiation are, great tenderness over

abdomen, rapidly developed ascites, rapid decline in strength and flesh, absence of jaundice, absence of long-continued dyspepsia, absence of hepatic changes on percussion, and the presence of tubercle or cancer deposits in other organs.

Prognosis. Terminates in death. Average duration after appearance of the dropsy, one year.

Treatment. For the changes in the hepatic structures, little, if anything, can be done; the following are some of the remedies recommended, to wit: hydrargyri chloridum corrosivum, gr. $\frac{1}{10}$ 0, three times a day; hydrargyri chloridum mite, gr. $\frac{1}{100}$ 0, three times a day; aurii et sodii chloridum, gr. $\frac{1}{20}$ 0, after meals; sodii phosphas, $\frac{1}{2}$ 0, after meals.

The diet must be regulated, *milk* being the most suitable, and avoiding fatty and saccharine foods.

The abdominal dropsy may be temporarily benefited by *purgatives* and *diuretics*, but sooner or later *tapping* becomes necessary.

AMVLOID LIVER.

Synonyms. Waxy liver; lardaceous liver; scrofulous liver; albuminous liver.

Definition. A peculiar infiltration into, or a degeneration of, the structure of the liver, from the deposit of an albuminoid material which has been termed *amyloid*, from a superficial resemblance to starch granules.

Causes. The chief cause is prolonged suppuration, especially of the bones; coxalgia; syphilis; cancer.

Pathological Anatomy. The liver is uniformly enlarged. It presents a pale, glistening, translucent appearance, and has a doughy consistency. On section, the surface is homogeneous, is anæmic and whitish. The deposit begins in the arterioles and capillaries, finally closing them.

The reaction with iodine and sulphuric acid affords a certain test of the amyloid or albuminoid deposits. After further cleansing, brush over the parts a solution of iodine with iodide of potassium in water, when they will assume a mahogany color, and if diluted sulphuric acid be added, a violet or bluish tint is produced.

A pretty reaction is to take a one per cent, solution of anilin violet, which strikes a red or pink color with the amyloid or albuminoid

material, while the unaltered tissues are stained blue, thus showing a beautiful contrast.

The amyloid change involves the spleen, kidney, intestines, and other organs.

Symptoms. Nothing characteristic. Hepatic dullness increased, with prominence over the liver; absence of pain; splenic dullness increased; emaciation and anæmia; urine increased in amount, pale, and containing some albumin, due to amyloid changes in the kidneys. Disorders of digestion, with diarrhæa, due to amyloid changes in the intestines. Jaundice is rare. Ascites seldom occurs.

Prognosis. Unfavorable. The progress is rapid or slow, depending upon the cause.

Treatment. No specific. Prof. DaCosta recommends ammonii murias, gr. x-xx, three times daily, for several weeks, then change for same length of time to syrupus ferri iodidum, beginning with mx gradually increased to f3j after meals, then to the former again, and so on, for months. Life may be prolonged by the use of ferrum, syr. calcii lactophosphas and oleum morrhuæ.

HEPATIC CANCER.

Synonym. Carcinoma of the liver.

Definition. A peculiar morbid growth, progressively destroying the hepatic tissue; characterized by disorders of digestion, anæmia, emaciation, jaundice, and ascites, and terminating in the death of the patient.

Causes. Hereditary, when it is termed *primary* cancer; extension from other organs, termed *secondary* cancer. It is a disease of advanced life, from forty to sixty years of age.

Pathological Anatomy. The most common variety of cancer of the liver is a compound of the medullary and scirrhus.

The cancer cells develop from the interlobular connective tissue, and as they grow the hepatic cells atrophy, the result of the pressure of the new growth. The branches of the hepatic artery enlarge and permeate the growth, while the branches of the portal vein are compressed and atrophied, thereby blocking up the portal circulation.

The cancer may develop in nodules or masses, or may be diffused; the nodules vary in size, and those on the surface are rounded, with a central umbilication. The peritoneum is adherent, cloudy, and thickened.

Symptoms. The development of hepatic cancer is preceded by a history of dyspepsia, flatulency, and constipation. Uneasiness, weight, and pain, increased by pressure, are noticed; jaundice, ascites, occasional intestinal hemorrhages, emaciation, feebleness, anamia, cold, dry, harsh skin, pinched features, with dejected, worn expression. Fever never occurs. The hepatic dullness is increased, with pains on palpation, and the liver is indurated, irregular and nodulated.

The duration is less than a year from the time the disease is recognized.

Diagnosis. The points of differentiation are the age, cachexia, pain, and tenderness, enlarged liver with hard nodules, and rapid emaciation and progress of the disease.

Prognosis. Always terminates in death.

Treatment. Early, symptomatic. Sooner or later *opium* must be used, to relieve the terrible and persistent pain.

DISEASES OF THE KIDNEYS.

THE URINE.

The *normal quantity* of urine varies from forty to fifty ounces in the twenty-four hours; it is *decreased* by free perspiration and *increased* by chilling of the skin.

Within the twenty-four hours, the least urine is passed at night, or in the early morning, very much the greater portion being passed during the course of the day.

The normal color is light amber, due to urobilin; the color deepens if the quantity voided be decreased, and vice versa. In nearly all normal urine a cloud of mucus forms, after standing a short time.

The normal reaction is slightly acid, due to the acid sodic phosphate, uric and hippuric acids. After meals it may be neutral or even alkaline.

The normal specific gravity varies from 1.015 to 1.020; it is low when an increased quantity is passed, and high when the quantity is diminished.

The normal odor of urine is a peculiar, well known, aromatic one

it is altered by certain foods, such as the violet stench after eating asparagus, and the garlicky odor after using garlic.

The most important organic and inorganic solid constituents held in solution are, urea (the index of nitrogenous excretion), from 308 to 617 grains daily; uric acid, from 6 to 12 grains; urates of sodium, ammonium, potassium, calcium and magnesium, from 9 to 14 grains; phosphates of sodium, etc., from 12 to 45 grains, and chlorides of sodium, etc., from 154 to 247 grains daily.

I. Quantitative test for *urea*, by hypobromite of sodium (Davy's method).

Fill a graduated glass-tube one-third full of mercury, and add one-half drachm of the 24 hours' urine; then fill the tube evenly full with a saturated solution of hypobromite of sodium, and close it immediately with the thumb; invert the tube and place its open end beneath a sat. sol. of chloride of sodium; the mercury flows out and is replaced by the solution of salt; nitrogen gas is disengaged from the urea in the upper part of the tube.

Each cubic inch of gas represents .645 gr. of urea in the half drachm, from which the amount passed in 24 hours may be calculated.

Urine containing an excess of urates and uric acid, on *cooling*, precipitates them (viz.: "brickdust deposits" in "pot de chambre"). *Heat* dissolves them to a certain extent.

Nitric acid deprives the soluble neutral urates of their bases, and produces, at first, a faint, milky precipitate of amorphous acid urates; adding more acid, the still less soluble red crystals of uric acid, resembling cayenne pepper, are deposited.

Put a small quantity of *nitric acid* in a test tube, and pour the urine carefully down the sides of the tube upon it, and a *zone* of *yellowish-red uric acid* and altered coloring matter will form at their union; and a dense, milky *zone* of *acid* urates above this, which, however, dissolve upon agitation. (See albumin test.)

II. Tests for *urates* and *uric acid* by nitric acid.

III. Quantitative test for *uric acid* by nitric acid.

IV. Test for the earthy and alkaline phosphates by the magnesian fluid.

V. Test for the *chlo-rides* by nitrate of silver.

VI. Test for *mucus* by acetic acid and liquor. iodi comp.

To three ounces of the 24 hours' urine (after being slightly acidulated, boiled, and filtered while hot) add one-tenth as much nitric acid; place in a cool place for 24 hours, then collect the deposit of uric acid on a weighed filter, wash it thoroughly, and dry at 212° F. The increased weight represents the uric acid in part excreted, approximately.

Heat or liquor potassæ increases the cloudiness caused by earthy calcium and magnesium phosphates. Acetic or nitric acid clears it by dissolving them.

To two ounces of urine add one-third as much of the following solution: R. Magnesii sulph., ammonii chloridi puri, liquor ammoniæ, each one part; aquæ destil., eight parts; if the precipitate has a milky, cloudy appearance, the quantity of phosphates is normal; if creamy, the phosphates are in excess.

To a convenient quantity of urine add a small amount of nitric acid, to prevent the formation of the phosphates and other salts of silver; filter this, if cloudy; add to this one drop of a solution of nitrate of silver (I part to 8) and the precipitate of white cheesy lumps of chlorides of silver denotes that the amount of chlorides are normal; if, however, only a faint milkiness occurs, the chlorides are diminished.

Mucus alone is not visible, but causes cloudiness, from having entangled mucus or pus corpuscles, epithelium, granules of sodium urate, crystals of oxalate of lime, and uric acid in various amounts.

Add to the urine a little acetic acid, or, in addition, a few drops of liquor. iodi comp., when threads and bands of mucin are made visible. The addition of nitric acid dissolves them.

VII. Test for albumin by heat and nitric Slightly acidulate the urine, if necessary, by addition of nitric or acetic acid, and boil; this causes a white deposit of coagulated albumin, which is not dissolved by nitric acid, unless the acid is in excess.

Nitric acid causes a white deposit of coagulated albumin, which is dissolved if a large excess of acid be added. A delicate test is to put the nitric acid in the tube first, and then gradually pour the urine down the side of the tube upon it, when a white zone or ring of coagulated albumin appears. Precaution, see tests Nos. 3, 4, 11, and 13.

VIII. Test for *albu-min* by picric acid (saturated, watery solution).

Pour a quantity of urine into a test-tube, and add the *picric acid solution* drop by drop, and, as it passes through the urine, it is followed by an opaque white cloud if albumin be present. The test is very striking and beautiful. If cloudiness appears some time after, instead of at the time, it shows nothing. The test will not detect as small an amount of albumin as heat or nitric acid.

IX. Nitric-magnesian test for *albumin*. The fluid is prepared by mixing I part of pure nitric acid with 5 parts of a saturated solution of the sulphate of magnesium, and filtering.

One drachm of the reagent is poured into a perfectly clean test-tube; the urine should be allowed to trickle slowly down upon the fluid; if albumin be present in an amount as small as one one-hundredth of one per cent., this test will show a compact, dense, white layer. This is one of the best and most reliable tests for albumin.

X. Quantitative test for *albumin*. Approximately.

Add a few drops of *nitric acid* to a proportion of the urine, and *boil*; set this away for 24 hours, and the proportionate depth of the resulting deposit is the comparative indication, viz.: $\frac{14}{4} - \frac{12}{4}$, etc.

For minute traces of albumin Millard's fluid may be used; it is a delicate test and requires care. The fluid consists of glacial carbolic acid (ninety-five per cent.) 3ij; pure acetic acid, 3vij, liquor potassæ Zij, Zvi.

XI. Test for blood acid.

Heat or nitric acid causes deposit of albuby heat and nitric min, with the coloring matter changed to a dirty brown.

> Heat the urine, then add caustic potash and heat anew. The phosphates are thus precipitated, taking with them the coloring matter of the blood, which imparts a dirty, yellowish-red color to the sediment, viewed by reflected light, and when seen by transmitted light, gives a splendid blood-red color.

XII. Test for blood by heat and caustic potash (Heller's).

Neither the coloring matter of the blood, nor that of the bile, is precipitated with the phosphates, so that coloration of urine which shows this reaction cannot be ascribed to the presence of the latter pigments.

When the quantity of blood in the urine is very large, it is of a dark or brownish-red, and after standing, forms a coagulum of blood at the bottom of the vessel.

Caution. Heat or nitric acid causes coagulation of the albumin in pus.

XIII. Test for pus by liquor potassæ.

Add to the urine, or preferably to its deposit from standing, an equal volume of liquor potassæ; when well mixed, a viscid gelatinous fluid or mass is formed, which pours like the white of an egg, or jelly.

XIV. Test for bile by "fuming" or red nitric acid.

Allow a specimen of urine and a few drops of red "fuming" nitric acid to gradually intermingle on a porcelain dish, and a "play of colors," green, blue, violet, red and yellow or brown, occur, if biliary coloring matter be present.

Pour into a test tube about 1.6 f2 of pure

Pour into a test tube about 1.6 f3 of pure hydrochloric acid, and add to it, drop by drop, just sufficient urine to distinctly color it. The two are mixed. Then drop down the side of the test-tube pure nitric acid, which will "underlay" the mixture of hydrochloric acid and urine. At the point of contact between the mixture and the colorless nitric acid a handsome "play of colors appears." If the "underlying" nitric acid is now stirred with a glass rod, the set of colors which were superimposed upon one another will appear alongside of each other in the entire mixture, and should be studied by transmitted light.

If the hydrochloric acid, on addition of the biliary urine, is colored *reddish-yellow* the coloring matter is *bilirubin*; if it is colored *green*, it is *biliverdin*.

Add to the urine half its volume of liquor potasso. (Caution. This may give a white, flaky precipitate of the earthy phosphates, which should be removed by filtering.) Now boil; this causes, at first, a yellow-brownish color, becoming darker if much sugar is present, due to glucic, and finally to melassic acid.

Add to the urine half its volume of liquor potassæ, and then a little bismuth subnitrate, shake and thoroughly boil; the presence of sugar reduces the salt and black metallic bismuth is deposited, or if but little sugar, a gray deposit occurs.

Caution. Albumin must be absent.

XV. Test for *hile* pigment by pure hydrochloric and pure nitric acids (Heller's).

XVI. Test for *sugar* by liquor potassa and heat (Moore's).

XVII. Test for sugar by subnitrate of bismuth, liquor potassæ and heat.

XVIII. Test for sugar by a solution of cupric sulphate, liquor potassæ and heat (Trommer's).

Now boil, and a yellowish precipitate of hydrated cupric suboxide, occurring at once, denotes the presence of sugar.

Caution. Albumin must be absent.

Take of Pavy's solution of cupric protoxide, recently prepared (see margin), 200 minims or a multiple of this quantity and

XIX. Quantitative test for sugar by Pavy's solution, to wit:—

R.
Cupric sulphate, gr. 320
Neutral potassic
tartrate, . gr. 640
Caustic potash, gr. 1280
Distilled water, f 3 20
Keep corked.

XX. Quantitative test for *sugar* by fermentation and the specific gravity.

Take of *Pavy's* solution of *cupric protoxide*, recently prepared (see margin), 200 minims or a multiple of this quantity, and *boil* in a porcelain dish; while boiling, add minim by minim, from a measured portion of the 24 hours' urine, and it gives a *yellowish* precipitate of *hydrated cupric suboxide*, if sugar be present.

Add to the urine a few drops of a solution of *cupric sulphate*, and then its own volume of *liquor potassæ*. (Caution. On first addi-

tion a light greenish precipitate occurs,

which, on further addition of the reagent, if

sugar or certain other organic matters are

dissolved, giving a transparent blue liquid.)

Note carefully the gradual disappearance of the blue color, and when completed (best determined by looking through the margin of the fluid against the white porcelain dish) from the amount of urine used, determine the amount of sugar passed daily. The quantity of urine containing one grain of sugar being just sufficient to reduce the 200 minims of the copper solution.

Take two measured specimens from the 24 hours' urine, and to one add a little yeast. Place each specimen in a temperature of 75° to 80° Fah.; in 24 hours, fermentation having destroyed the sugar in the one containing the yeast, the difference in the specific gravity of the two specimens expresses the number of grains in each ounce of the urine. Approximately.

CONGESTION OF THE KIDNEYS.

Synonyms. Renal hyperæmia; catarrhal nephritis.

Definition. An increase in the amount of blood in the vessels of the kidneys; when arterial, it is termed active congestion; when venous, passive congestion; characterized by pain, frequent desire for urination, the amount of urine scanty, high-colored, occasionally containing albumin or blood.

Causes. Active; from cold; irritating substances eliminated by the kidneys, as turpentine, copaiba, cantharides, carbolic acid, nitrate or chlorate of potash; during the eruptive or continued fevers; injuries over the kidneys.

Passive; obstructive diseases of the heart or lungs, pressure of the pregnant uterus.

Pathological Anatomy. The kidneys enlarge and increase in weight; increased redness (the color being bluish if passive), with points of vascularity, corresponding to the Malpighian bodies, and occasionally minute ecchymoses. The abnormal hyperæmia causes a catarrhal state of the ducts of the pyramids, with shedding of their epithelium.

If mechanical (passive) obstruction continues for some time, increase of the connective tissue, with consequent induration and contraction results, or a form of chronic Bright's disease.

Symptoms. Active variety; pain over kidneys and following the course of the ureters into the testicles and penis, irritable bladder, almost constant and pressing desire for urination, the urine scanty, high-colored, and occasionally bloody, with fibrin, casts and albumin; there is, as a rule, no pain during the act of urination. The constitutional symptoms are headache, slight nausea, vomiting, and a general feeling of discomfort.

If the condition persist, inflammation of the kidney results.

Passive; the kidney changes are masked by the *lung* or *heart* trouble, until *dropsy*, *scanty*, *high-colored*, *albuminous* urine is observed.

Prognosis. Active; if recognized and properly treated, favorable. Passive, controlled by the cause, and if prolonged, terminating in interstitial nephritis.

Treatment. The most important indication is to ascertain and remove the cause. Rest of the body; dry or wet cups over the loins:

dilute the urine by increasing the quantity of bland fluids consumed; saline purgatives; warm bath or other mild diaphoretics. Infusum digitalis is pre-eminently the remedy for congestion of the kidneys; if great irritability of the bladder, camphora, gr. ij-iv, every four hours, combined with morphinæ sulph., gr. $\frac{1}{12}$ - $\frac{1}{6}$, or the hypodermic injection of morphina, gr. $\frac{1}{12}$.

The treatment of the passive form resolves itself into the treatment of the cause, remembering that there is too much blood in the veins and too little in the arteries. There are three ways of restoring the circulation. By venesection, opening a large vein; by increasing the power of the heart by the use of digitalis or strophanthus, preferably the first named; and by dilatation of the capillaries with inhalations of amyl nitrite or the internal use of spiritus glonoini (nitro-glycerin I per cent. solution), one to three drops every four hours. The bowels should be kept soluble by salines.

ACUTE PARENCHYMATOUS NEPHRITIS.

Synonyms. Acute Bright's disease; acute desquamative nephritis; acute tubal nephritis; acute nephritis.

Definition. An acute inflammation of the epithelium of the uriniferous tubules; characterized by fever, scanty, high-colored or smoky urine, dropsy, with more or less constant nervous phenomena, the result of acute uræmia.

Causes. The young more liable than the aged; cold and exposure; scarlatina, diphtheria, and other infectious diseases; persistent use of irritants, as turpentine, cantharides, phosphorus, ginger, and others. Blows and injuries of the back have caused acute nephritis.

Pathological Anatomy. The kidneys are generally swollen, engorged, more vascular, and of red color; in the second stage the organ remains large, irregularly red, especially the cortex; the tubules are engorged and filled with epithelium, blood corpuscles and fibrin. The capsule is easily detached, and is more opaque than normal.

If a favorable termination, the swelling lessens, the vascularity diminishes, the tubules returning to a normal condition.

Symptoms. In mild cases the slowly developing *dropsy*, with anæmia, and *dyspnæa*, or simply shortness of breath, with weakness, are the only clinical phenomena present, the diagnosis being con-

firmed by an examination of the urine. Usually, however, begins suddenly. Fever, with nausea and violent and persistent vomiting, dull pain over the kidneys, following the ureters; frequent desire to urinate; diarrhœa; skin harsh and dry; pulse quick, tense, and full. Soon dropsy appears, the eyelids and face become puffy and swollen, followed by general ædema of the extremities, scrotum, and abdominal walls. If the attack follow scarlatina there are from the onset much greater pallor and general debility.

Uræmic symptoms may develop any time during the attack.

The *urine* is of high specific gravity, scanty, smoky (like beef washings) in color, due to the presence of *blood*. *Albumin* is present in large quantities, and the microscope reveals *casts* of the uriniferous tubules, blood corpuscles, uric acid, urates and oxalate crystals, and epithelium.

Duration from one to four weeks.

Complications. Pericarditis, pleuritis, pneumonitis, peritonitis, and acute uræmia, from retention and decomposition of urea in the blood.

Diagnosis. The history, fever, scanty, smoky, albuminous urine, with dropsy beginning in the face, should prevent any error.

Albuminuria may be confounded, on account of the presence of albumin in the urine, but lacks the clinical history, usually occurring in the course of some constitutional affection, as diphtheria, cholera, yellow fever or erysipelas.

Da Costa distinguishes between acute Bright's disease and acute nephritis by the last named "affecting only one kidney, by much greater pain and tenderness in the lumbar region, by the retraction of the testicle, and by the higher degree of febrile excitement. Then, too, the deeply-colored urine which is voided contains little or no albumin."

Prognosis. Favorable. Majority of cases recover under prompt treatment. Rarely passes into chronic Bright's disease. *Uræmic* symptoms add to the gravity of the prognosis.

Treatment. Absolute rest in bed until all symptoms have disappeared. A strictly milk diet is the most suitable, but if there is much depression and weakness, may add animal broths and oysters. No tea, coffee or stimulants. Water can be used ad libitum. Cream of tartar lemonade is a useful as well as pleasant drink. Locally, dry cups over the kidneys followed by poultices—a digitalis poultice being the very best.

The bowels should be kept soluble with morning doses of salines, or pulv. jalapæ comp., 3j, in water before breakfast, or elaterium, gr. ½ repeated p. r. n. Free action of the bowels assists in relieving the overtaxed kidneys, and conjoined with free diaphoresis seems almost indispensable in acute nephritis. Magnesii sulphas, in small and repeated doses, is a valuable cathartic in nephritis, as it acts upon the kidneys as well as the bowels.

The most efficient diaphoretics are, the hot-air bath or pack, or the wet sheet and blanket bath, stimulating the peripheral circulation after free sweating has occurred by rubbing with alcohol and water. For drugs, one of the very best is extractum pilocarpi fluidum, mx-xxx, every three or four hours; but as it is generally conceded that pilocarpus acts better when administered subcutaneously, employ pilocarpinæ hydrochloras gr. ½, repeated p. r. n., by the hypodermic method. Another valuable diaphoretic is vinum ipecacuanhæ, gtt. j-iii, every half hour or so.

Diuretics are of great value, indeed, often indispensable in acute nephritis. The following formula of Millard's is suitable in the majority of cases:—

R.	Tinct	t. digital	lis,										. f 🕱 s	s	
		scillæ,													М.
		ætheris													TAI *
SIG	—Tea	spoonfu	lev	ery	th	ree	or	. 10	our	hc	ours	s in	water.		

The following combination has given excellent results:-

0 .02.	0 1 6				0.							
R.	Potassii acetat.,										. 3 iv-vj	
	Inf. digital., .											
	Liq. potassii citi										. f ℥ iij.	M
Stg.	—Tablespoonful	ever	v f	ou	r h	our	s ir	W	ate	r.		

Other reliable diuretics are digitalinum (cryst.), gr. $\frac{1}{100}$; caffeinæ citras, gr. $\frac{1}{100}$; or sparteinæ sulphas, gr. $\frac{1}{3}$ - $\frac{1}{2}$.

If uræmic symptoms, treat according to directions given in that section.

As soon as the blood disappears from the urine, a course of *ferrum*, in the shape of *Basham's mixture*, until albumin disappears and health is restored. The following is the formula of Basham's mixture:—

_								
R .	Liq. ammon. acetat.,							
	Acid. acetic.,			٠	٠	٠		3 iij
	Tinct. ferri chlor., .							fzv
	Alcoholis,							Ζij

	Aquæ,							
SIC	- Dose fri-fri							- 69

М.

CHRONIC PARENCHYMATOUS NEPHRITIS.

Synonyms. Chronic Bright's disease; chronic croupous nephritis; chronic tubal nephritis; chronic albuminuria; large white kidney.

Definition. A chronic inflammation of the cortical and tubular structure of the kidneys; characterized by albuminous urine, dropsy, increasing anæmia, with attacks of *acute uræmia*.

Causes. Rarely follows the acute form, but in ever so many cases the etiology is unknown, and in the vast majority of cases it is primarily chronic or subacute; syphilis; chronic malaria; alcoholic excesses; chronic mercurialism; lead poisoning; opium habit; protracted suppuration; phthisis; hepatic disorders; pregnancy; some undetermined nervous condition.

It is a disease of the young, rarely occurring after forty.

Pathological Anatomy. A large white, or yellowish white, smooth kidney, often twice the normal size. The capsule is nowhere adherent to the organ. Upon section, considerable tumefaction of the cortical substance and the rarity of vascular striæ are recognized. The medullary substance shows no appreciable alteration, its color being normal. The convoluted tubes are irregularly dilated and thickened, and filled with broken-down, granulated epithelium and fibrinous casts. In pronounced cases there is fatty degeneration of the tubular epithelium.

"The intertubular matrix is greatly thickened—a change due to hyperplasia of the connective-tissue elements, to the migration of the white corpuscles and their subsequent multiplication and fatty transformation, and to a quantity of fluid exudation, the product of the increased pressure in the veins."

Symptoms. The onset is gradual and insidious, and the affection is seldom recognized until the appearance of *dropsy*, which, beginning under the eyes and in the face, extends all over the body, causing *dyspnwa* from asciles or *hydrothorax*, although in many cases the dropsy is a late symptom, the patient becoming *pale*, *debilitated* and suffering from *cardiac palpitation*, increasing *dyspnwa*, and *vomiting*, all gradually developing without apparent cause; also *headache*, *vertigo* and *defective vision*. The *urine* is scanty, high-colored, *albuminous*, and under the microscope showing hyaline and

granular *tube casts*, granular epithelium, and if fatty degeneration occur, *fatty tube* casts and oil globules. The increase above the normal amount of the urine, as the disease progresses, must not be forgotten, when the specific gravity is low, 1.010–1.015, and the quantity of albumin is increased. Irritable bladder is a very constant symptom.

Anamia is pronounced, from the large waste of albumin. Gastro-intestinal disorders and vague neuralgic pains are common occurrences. Cardiac hypertrophy is of common occurrence. Bronchial catarrh, with slight adema of the larynx, causing husky voice, are frequent complications. Amaurosis, the result of neuro-retinitis, occurs in a greater or less degree in all pronounced cases. Uramic symptoms occur and especially uramic asthma (renal asthma).

Complications. Pneumonitis, pleuritis, pericarditis, peritonitis, meningitis, and cardiac hypertrophy.

Prognosis. Not unfavorable, unless urine persistently contains a large number of fatty tube casts and oil globules. Relapses are frequent, but many complete (?) recoveries are recorded. I have seen four apparent recoveries, one after twelve months' duration, another after two years' duration, and still another after five years' duration, no return showing itself after two years.

Treatment. It is to be borne in mind that the course of a case of chronic Bright's disease is not continuously downward; periods of remission often follow the most aggravated symptoms, the patient and his friends being buoyed into the hope of an early and complete recovery, when, as suddenly, an attack of acute uræmia terminates life.

Rest and diet are important elements in the treatment.

A patient with chronic Bright's disease should, as far as possible, be relieved from all cares of business and spend a goodly portion of time in bed.

The *diet* is of prime importance. It may consist of an absolute *milk* regimen, pure, or prepared as most palatable, or an exclusive *lean meat* diet, prepared by finely chopping, removing all fibrous and fatty portions, boiled quickly, salted to taste, and served hot. The use of half a pint of hot water, acidulated with lemon, before each meal is valuable.

The use of diaphoretics and hydragogue cathartics are only indi-

M.

cated when the dropsy is marked, the skin harsh and dry, the urinary secretion scanty, and uræmic symptoms are threatening, for which administer the following:—

Sig.—Three times daily for a few days.

Diuresis should be promoted, if the secretion of urine is scant, by digitalis, caffeinæ citrata or sparteinæ sulphas., internally or hypodermically, or spiritus glonoinis, and dry cups and poultices over the loins.

Iron is preëminently the drug for this variety of Bright's disease; the tinctura ferri chloridum or the albuminate are the best forms for administration.

The anæmia is to be treated by oleum morrhuæ, arsenicum and ferrum, an excellent formula for the latter being—

R.	Strychninæ sulph.,							gr. 1/4
	Tinct. ferri chloridi,							
	Acidi acetici puræ,							
	Curacoæ albæ,							
	Liq. ammonii acetat.,	,			٠	ad		f Z vi.

Sig.—Tablespoonful every five hours, followed by a glass of cold water.

To check the waste of albumin, a difficult matter, the following remedies have been used with more or less success: ergota, quinina, acidum gallicum, sodii benzoas, tinctura cantharidis, or potassii iodidum.

For dropsy, purgatives, such as pulvis jalapæ compositus, magnesii sulphas, and alkaline mineral waters; act on skin with vapor baths, or pilocarpinæ hydrochloras, gr. ½, repeated if not much cardiac depression, or combining pulvis ipecacuanhæ et opii, gr. iij, with potassii nitras, gr. iij-v every two or three hours, or, what is most valuable, the hot-air bath or pack. If there be great distention of the serous cavities, interfering with the respiration, the aspirator should be used. Puncture of the skin may be necessary at times, and it is well accomplished with an ordinary cambric needle.

Cases due to *syphilis*, if the loss of renal structure is slight, are cured by a course of *hydrargyri corrosivum chloridum* and *potassii iodidum*, with *oleum morrhuæ*.

INTERSTITIAL NEPHRITIS.

Synonyms. Chronic Bright's disease; sclerosis of the kidneys; contracted kidneys; small red kidney; gouty kidney.

Definition. An inflammation of the intervening connective tissue of the kidney, chronic in its progress, resulting in an induration or hardening, with contraction of the organ; characterized by frequent voiding of large amounts of pale, albuminous urine, of low specific gravity, disorders of the gastro-intestinal and nervous systems, and a strong tendency to cardiac hypertrophy and changes in the vessels. Cases of nephritis are not uncommon in which albumin is never detected in the urine.

Causes. A disease of middle life, from forty to sixty years. Gout a common cause; lead cachexia; syphilis; alcoholism; opium habit; long-continued worry, anxiety or grief; alterations in the renal ganglionic centres (DaCosta and Longstreth).

I have slowly become convinced that the large increase of nephritic cases can be attributed to the widespread use of drugs of the salicylic order.

Pathological Anatomy. The kidneys are reduced in size. The capsule is thickened, opaque, and adherent. The surface of the kidney is granular, with cysts of various sizes, of transparent color, scattered irregularly over the surface. On section the tissue of the kidney is tough and resistant. The cortical portion is thin, from atrophy, being only a line or two in thickness. The connective tissue is greatly thickened, compressing the tubules into mere threads, the glomeruli being grouped together in bunches, owing to the wasting of the intermediate tubes. The color varies, from a darkish-brown to a yellowish-gray, according to the amount of blood in the organ.

The left side of the *heart* is hypertrophied, and there is also hypertrophy of the muscular fibre of the *arterioles* throughout the body; if the case is protracted the hypertrophied tissues undergo fatty degeneration.

In many cases there occur fatty degeneration of the retinal tissues, or sclerosis of the nerve-fibre layer, changes which are termed retinitis albuminurica.

The "ganglionic centres" undergo fatty degeneration and atrophy (DaCosta and Longstreth).

Apoplexy is a frequent termination of interstitial nephritis, the rupture of a cerebral vessel suggesting it to be a disease of degeneration.

Symptoms. Onset insidious, and often marked alterations in the kidneys, heart and vessels have occurred before the disease is recognized. There are no characteristic early symptoms in the majority of cases, the disease being apparently latent, until some special outbreak cause a more thorough examination of the patient, when interstitial nephritis is detected.

Any of the following symptoms may first attract attention: Frequent micturition, increased amount of urine, of a pale color, low specific gravity, containing a small amount of albumin, which may be absent for days, occasional epithelial cells and hyaline casts. No dropsy, but a little puffiness and adema of the conjunctiva—the Bright's eye. Disorders of vision. Forcible cardiac action with high arterial tension. Attacks of vertigo, headache, disordered vision, attacks of epistaxis and disordered stomach. Progressive anæmia is a frequent symptom. Any of the following symptoms, the result of uramia, may occur: Persistent dyspepsia, occasional vomiting, regardless of food; headache, vertigo, and stupor, or drowsiness; violent itching of the skin; tremors, convulsions, epileptic seizures, or apoplectic attacks.

The body weight declines, the skin is dry and scurfy, the strength fails, and shortness of breath on exertion is present.

The termination is usually by convulsions, coma, and death.

Complications. Bronchitis; pneumonitis; pleuritis; pericarditis; cardiac hypertrophy.

Diagnosis. Interstitial nephritis is most likely to be confounded with parenchymatous nephritis. The following table from Millard presents the most important points of difference between the two:—

IN CHRONIC CROUPOUS NEPHRITIS.

The urine is always albuminous. Urine usually scanty.

Dropsy and cedema almost always occur.

Hypertrophy of the heart seldom exists.

Specific gravity of urine usually higher than the normal. Urine darker and with less of a soapy appearance than in chronic interstitial nephritis.

IN CHRONIC INTERSTITIAL NE-

Urine not constantly albuminous. Urine usually abundant.

Dropsy seldom or never present; sometimes slight ædema.

Some hypertrophy of heart with increased arterial tension almost always present.

Urine generally of a light color and low specific gravity.

IN CHRONIC CROUPOUS NEPHRITIS.

Uræmic symptoms less frequent than in chronic interstitial nephritis.

Epistaxis and cerebral hemorrhages

Occurs most frequently before the age of forty.

Blood corpuscles and connective tissue shreds more frequently found in chronic croupous nephritis.

Casts more numerous and in greater variety than in chronic interstitial nephritis; waxy, granular, fatty, and hyaline casts occurring.

Epithelia from the kidney and pus corpuscles more numerous than in interstitial nephritis.

Urates and phosphates predominate; oxalates rare.

Albuminous retinitis rare.

Gangrenous erysipelas and phlegmenous swellings more common; also dyspepsia and anæmia.

Visceral complications, as pneumonia, pleuritis, pericarditis, and bronchitis, not uncommon.

Diarrhœa sometimes.

Cirrhosis of liver rare.

Atheroma of arteries rare.

IN CHRONIC INTERSTITIAL NE-

Uræmic symptoms are met with in their most pronounced form, and in severe cases usually occur.

Epistaxis and cerebral hemorrhages frequent.

Occurs most frequently after forty.

Absent in chronic interstitial nephritis.

Development more gradual, the health of patient often less impaired, and duration longer than in chronic croupous nephritis.

Casts rare, the hyaline variety being most frequently met with.

Kidney epithelia and pus corpuscles scanty, and occasionally absent.

Oxalate of lime almost always oc-

Albuminous retinitis common.

Visceral complications rare.

Cirrhosis the most frequent hepatic

Atheroma common.

Prognosis. Pursues a very chronic course; cases recorded under observation eleven years. If the case is seen in its incipiency a cure is possible, but as a rule we say the termination is fatal.

Treatment. Regulated diet; diaphoretics; diuretics; avoid alcoholic stimulants. As nearly absolute rest as patient's general

health will permit.

To prevent the growth of the connective tissue, the following remedies are recommended: potassii iodidum, hydrargyri corrosivum chloridum, gr. 15. aurii et sodii chloridum, gr. 15. ferri iodidum, and arconicum

Ferrum is as valuable in this as in the other forms of Bright's

For uramia, if patient is conscious, purgatives, diaphoretics, and diuretics. If unconscious, hot air bath, morphina and pilocarpina hydrochloras, or caffeinæ citrata., hypodermically, or chloroform inhalations, and watching the heart.

AMVLOID KIDNEY.

Synonyms. Chronic Bright's disease; waxy kidney; lardaceous kidnev.

Definition. A peculiar infiltration into, or a degeneration of, the structure of the kidney, from the deposit of an albuminoid material, having a superficial resemblance to molten wax or boiled starch. Similar changes occur in the liver, spleen, intestines, and other organs.

Causes. The chief cause is prolonged suppuration, especially of

the bones; coxalgia; syphilis; cancer; phthisis.

Pathological Anatomy. The kidney is uniformly enlarged. It presents a pale, glistening, translucent appearance, and has a doughy consistency. On section, the surface is homogeneous, anæmic, and whitish. The deposit occurs along the renal vessels and in the vascular tufts of the glomeruli, progressing until all parts of the organ are infiltrated. When the organ is thus infiltrated, the proper structure undergoes an atrophic degeneration, the result of pressure.

The reaction with iodine and sulphuric acid affords a certain test of the amyloid deposit. Brush over a section of the affected kidney a solution of iodine with iodide of potassium in water, when a mahogany color will be produced, and if diluted sulphuric acid is now added, a violet or bluish tint results. A very pretty reaction is to take a one per cent. solution of anilin violet, which strikes a red or pink color with the amyloid material, while the unaltered tissues are stained blue, making a beautiful contrast.

Similar changes occur in other organs of the body. With the amyloid change may be associated either parenchymatous or interstitial nephritis.

Symptoms. Associated with wasting are wdema of the lower extremities and ascites, with an increased flow of urine, pale, watery, and of low specific gravity, containing albumin and hyaline casts, which are transparent. If the amyloid change be associated with other forms of renal change, the urine will show the characteristics of such condition. A profuse, watery, and persistent diarrhwa caused by the amyloid changes in the intestinal canal.

Diagnosis. Differs from *parenchymatous nephritus* in its clinical history, and the fact of its always being associated with a suppurating disease.

From *interstitial nephritis*, in its history, character of the urine, *absence* of uræmia, cardiac hypertrophy, changes in the vessels, and the fact of its association with suppurating diseases and similar changes in other organs.

Prognosis. Controlled by the suppurating disease with which it is associated; the termination, when the amyloid change is fully developed, is unfavorable, death occurring within a few months, or, under favorable conditions, not for one or more years.

Treatment. Sustaining and symptomatic in character. Generous diet and the persistent use of ferri iodidum, alternating with ammonii murias and oleum morrhuæ.

If caused by syphilis, a thorough course of potassii iodidum, ferri iodidum, and hydrargyri corrosivum chloridum, with oleum morrhuæ.

If of syphilitic origin, the plan of Keyes (Dr. E. L.) is to be commended: "I think that a case treated from the first should receive mercury continuously in *small doses* (gr. $\frac{1}{35}$ to gr. $\frac{1}{50}$), for a period not less than two and a half years, or, in any event, until at least six months have passed after the entire disappearance of the clearly syphilitic symptoms."

PYELITIS.

Synonyms. Suppurative nephritis; pyelo-nephritis.

Definition. An acute catarrhal inflammation of the pelvis of the kidney; the term *pyelo-nephritis* is used when suppurative inflammation is superadded to the catarrhal inflammation. The disease is characterized by lumbar pains, irritability of the bladder, the urine

neutral or alkaline in reaction and milky in appearance; if *pyelo-nephritis* occur, symptoms of hectic fever and exhaustion are added, the urine containing pus.

Causes. Cold or exposure; cystitis; obstruction of the ureters by renal calculi; pressure from a tumor; prolonged use of bromides and other irritative drugs; rheumatism; sequelæ of infectious diseases.

Pathological Anatomy. The inflammation is catarrhal; it is characterized by injection of the mucous membrane of the pelvis of the kidney, with slight extravasations of blood; relaxation and softening, shedding of the epithelium, and the subsequent discharge of mucus and pus. If the morbid condition has existed for some time, the kidneys, one or both, are in a process of suppuration, they are enlarged, deeply congested, except where suppuration is proceeding, when they are of a yellowish-white color—pyelo-nephritis. Pus is constantly forming, and, if there be no obstruction, flows away with the urine; should there be an impediment to its escape, pus accumulates in the pelvis of the kidney, causing its distention, giving rise to the condition known as pyelo-nephrosis. The pressure caused by the obstruction finally leads to destruction of the entire organ, a mere sac, or renal cyst, remaining.

Symptoms. If caused by *cystilis*, symptoms of this condition occur first; if from *renal calculi*, its characteristic symptoms precede those of pyelitis.

Begins by chilliness, feverishness, lumbar pains following the course of the ureters, frequent micturition, the urine milky in appearance when voided, acid or neutral in reaction, and depositing a copious sediment, whitish or yellowish-white in color, containing only a small amount of albumin, no more than is due to the pus.

Cases of pyelitis due to renal calculi frequently show hemorrhages; the urine bloody after some extra exertion.

If pyelo-nephritis follow, symptoms of pyæmia supervene, to wit: fever, typhoid in character, low, muttering delirium, subsultus tendinum, stupor, decline in strength, and loss of flesh, with perhaps a tumor in the lumbar region.

If both kidneys are affected uramic symptoms are frequent.

Diagnosis. From *cystitis*, by history, lumbar pains and *acidity* of purulent urine, the urine in cystitis being always *alkaline*. A microscopical examination of the urine will aid the diagnosis very much.

Perinephritis, a disease of the loose tissue, around about the kidneys, terminating in abscess, causing lumbar pain, increased by motion or pressure, hectic fever, sense of fluctuation over kidneys, the urine remaining normal.

Prognosis. Simple cases, where no obstruction to flow of pus, *recover* in a week or ten days. If obstruction of the ureter, the prognosis is grave. Suppurative cases unfavorable.

Treatment. Rest in bed. Milk diet. Free use of water to dilute the urine, and free diaphoresis. *Quinina* to keep down temperature, prevent formation of pus, and maintain the powers of life.

To change the character of the secretion, Prof. Da Costa strongly recommends pix liquida; other remedies are oleum santali, copaiba, eucalyptol, terebinthina, and cubeba. I have seen excellent results from a prolonged course of the Buffalo Lithia Springs water or the Rockbridge Alum Springs water of Virginia.

For renal hemorrhage, alumen, gr. xx, repeated p. r. n., is successful.

If abscess results, aspiration, quinina, and stimulants. Extirpation of the diseased kidney has been followed with fair health.

ACUTE URÆMIA.

Synonyms. Uræmic poisoning; uræmic intoxication; uræmic coma; uræmic convulsions.

Definition. A group of nervous phenomena, which occasionally develop during the course of acute or chronic Bright's disease, and other maladies, the result of the retention or accumulation in the blood of an excrementitious material, supposed to be *urea*, the flow of urine being either normal, lessened, or increased.

Causes. Suppression of urine, from acute or chronic Bright's disease, probably more frequent in chronic parenchymatous nephritis; cystic, tubercular, or cancerous kidney; the puerperal state; operations on the uterus, bladder, urethra, or rectum.

Symptoms. Uramic intoxication is the result of the failure of the kidneys to perform their normal function of eliminating some one or all of the poisonous elements of the urine.

The toxemia may develop suddenly, by a convulsive seizure followed by coma, or slowly and gradually. Usually the attack is preceded by a decrease in the urinary secretion and slight or marked

cedema in various parts of the body; although it must be borne in mind that in rare instances, during, or immediately prior to, the appearance of the uræmic phenomena, the normal urinary flow has been largely exceeded.

The acute outbreak may manifest itself in a variety of ways.

Gastro!intestinal variety. The patient suddenly experiences attacks of vertigo, pallor of face, nausea and vomiting, with fever, the temperature varying between 100° and 103°, pulse tense and rapid, respiration hurried, and the urine scanty with low specific gravity; unless symptoms are promptly relieved convulsions may occur, followed by coma and death, or drowsiness supervene, followed by coma, which is really nothing but a profound sleep. Rarely an acute maniacal outbreak follows the gastro-intestinal symptoms.

Convulsive variety. Without any appreciable prodromes, epileptiform convulsions, with or without loss of consciousness. The convulsions may consist of a single paroxysm, or a succession of fits may follow one another at intervals of a few minutes or several hours, the patient in a condition of more or less profound insensibility during the intervals. The fits almost exactly simulate true epilepsy. In this variety the temperature is high, from 103° to 106° or more, the pulse rapid, with or without tension, the respirations quickened. Coma followed by death is a very common ending of this variety of uræmia, or after a profound sleep of hours the patient gradually recovers his usual health. Alcoholic excesses are responsible for many of these attacks.

Cerebral variety, or uræmic coma. Develops either gradually with an increasing drowsiness associated with headache, and irritability of temper (mild mania). Nausea, vomiting and rise of temperature, often reaching 105°, rarely 107°, with rapid, full pulse, or the patient may fall suddenly into a condition of profound coma, the symptoms closely resembling an apoplectic stroke, except the high temperature. Uræmic coma is always accompanied with rise of temperature and stertor. "The stertor is peculiar; it is not the "snoring" of apoplexy, but a sharp, hissing sound produced by the rush of expired air against the teeth or hard palate." (Loomis.) The respirations are accelerated, the pulse rapid but minus tension. This variety may suddenly terminate fatally with a convulsion, or a deepening coma with prostration and cold, wet skin, with ædema of the lungs, or rarely, gradual recovery.

Diagnosis. Uramic conditions closely resemble a number of conditions in which convulsions and coma are prominent symptoms. Much valuable assistance is obtained in the diagnosis by a knowledge of the condition of the kidneys. Always obtain a specimen of urine at once and subject to an albumin test at least.

Another valuable aid is the temperature record. I believe acute outbreaks of uræmia are always associated with a rise of temperature. The temperature is the result of the irritation of the heart-centres and not due to an increased arterial pressure.

Cerebral apoplexy may be mistaken for uræmic coma, or the reverse. The chief points of distinction are, in the latter the attack is usually in patients suffering from dropsy, and that the coma is not sudden in its appearance, but is generally preceded by other nervous phenomena, such as headache, vertigo, dimness of vision, obstinate vomiting, and convulsions. Again, the *uræmic stertor* is a sharp, hissing sound, while that of apoplexy is "snoring." Apoplexy is followed by paralysis, uræmic coma is not.

An *epileptic* seizure is preceded by the sharp cry and extreme pallor of the face, the countenance being dusky in uræmic convulsions.

Prognosis. An attack of acute uræmia is always a very grave condition. The prognosis depends upon the amount of retained poison, the length of time it has been retained, and the condition of the organs of elimination.

Treatment. Promptness and thoroughness is the essential point in the treatment of an uræmic outbreak.

For the gastro-intestinal variety, put patient to bed and administer the magnesium sulphate enema given below and order either caffeina citrata, gr. iij, every three hours, or the spartein and pilocarpine mixture mentioned below. As soon as the secretions have been started give one of the following powders every two hours until a dozen or more are used, followed by Hunyadi Janos water (R. Hydrargyri chlor. mitis, gr. $\frac{1}{4}$ - $\frac{1}{2}$; sodii bicarb., gr. ij; pulv. ipecacuanhæ, gr. $\frac{1}{6}$ -M. et. ft. chart. No. j).

For the convulsive or cerebral variety, the indications are: first, to arrest the nervous phenomena; secondly, to promote elimination. Prof. Loomis has succeeded in meeting both of these indications by hypodermic injections of morphina, gr. ½-½, repeated, if required, every two hours. He says: "The most uniform effect of morphine so administered is, first, to arrest muscular spasms;

second, to establish profuse diaphoresis; third, to facilitate the action of cathartics and diuretics, especially the diuretic action of digitalis."

Following the injection of morphina, diaphoresis should be promoted by means of the hot-air bath, or the hot-wet pack, or the hypodermic use of the pilocarpinæ hydrochloras, gr. $\frac{1}{12}$ - $\frac{1}{6}$ - $\frac{1}{4}$, provided no counter-indication to its use exists, or using at the same time frequent doses of caffeinæ citrata, gr. iij, by hypodermic injection.

The following combination has given excellent results in a number of cases when the patient was able to swallow:—

Sig.—Teaspoonful every half hour, hour, or two hours until effect.

If patient is unable to use the medicine by stomach the same drugs can be used by the hypodermic method, using digitaline cryst. (R. Digitalinæ cryst., gr. $\frac{1}{100}$; pilocarpinæ hydrochlor., gr. $\frac{1}{100}$; sparteinæ sulph., gr. $\frac{1}{100}$; aquæ destil. $\frac{1}{100}$ xxx. M. Sig: As dose p. r. n.)

I have never observed the alarming symptoms of depression from the careful use of pilocarpine, mentioned by some observers.

The production of free diaphoresis alone must not mislead the physician, as unless the sweat contains urea or its products it is only depressing, and the clinical fact is that in uræmia the eliminating function of the skin as well as the kidney is in abeyance.

The convulsions are rapidly controlled by inhalations of chloroform, (although the after symptoms are badly influenced by the drug), or the internal or rectal administration of full doses of chloral, or in suitable cases by a free venesection. It not infrequently happens that upon opening a vessel the blood does not flow, or but a few drops slowly flows from the wound. If this obtains it is almost immediately changed by a hypodermic injection of amyl nitrite, myj, with spts. ammoniæ aromaticus, mxv.

Diuresis is promoted by infusum digitalis, dry or wet cupping, poultices over the loins, and hot compresses of infusum digitalis over abdomen, or caffeinæ citrata, or sparteinæ sulphas, or spiritus gloinoini.

Catharsis is best promoted by elaterium, gr. $_{12}^{-1}$, or an Epsom salts enema. (R. Magnesii sulph., $\bar{\mathfrak{z}}$ ij; glycerini, $\bar{\mathfrak{z}}$ j; aquæ bul., $\bar{\mathfrak{z}}$ iv. M. as enema.)

The febrile phenomena does not call for antipyretics. It is one of

the nervous phenomena of uraemia and is controlled by the means employed to eliminate the poison.

If symptoms of collapse develop, with cold, clammy skin, feeble, rapid pulse, and superficial respirations, at once administer *atropina* sulphas, gr. $\frac{1}{60}$, and bathe surface with hot water and alcohol.

Of late sodii benzoas, 3j-ij, during the twenty-four hours has been lauded as an almost specific in uræmic intoxication. Under the action of this remedy the paroxysms lessen in severity, the intervals grow longer, and the convulsions after a time cease entirely. Profound sleep is induced by it, and during this the cerebral functions are restored. When albuminuria exists, a marked diminution occurs in the quantity present, or the albumin disappears entirely.

Milk, in as large quantities, diluted, as can be borne, should be the diet. The attack broken, the treatment resolves itself into that of the

nephritic affection causing it.

RENAL CALCULI.

Synonyms. Nephro-lithiasis; gravel; renal colic.

Definition. Renal calculi are concretions formed by the precipitation of certain substances from the urine, around some body or substance acting as a nucleus.

Their presence may not be recognized until one or more attempt to pass along the ureters, when an attack of *renal colic* results; or, by irritation, *pyelitis* is produced; or, more rarely, they are voided by the urine without exciting any symptoms.

By gravel is meant very small concretions (sand), which are often

passed in the urine in large numbers.

Causes. Occur at all ages; frequent before the fifth year, and from five to fifteen. Males are more liable than females. A special liability seems to exist in some families, but the precise etiology of calculi is not yet determined.

Varieties. 1. Uric acid, as calculi and gravel, and especially associated with the gouty diathesis.

- 2. Urates, chiefly urate of ammonium; nearly always in childhood.
- 3. Oxalate of lime or mulberry calculus; characterized by hardness, roughness, and very dark color.
- 4. Phosphatic calculi form as frequently in the bladder as in the kidney, and present a chalky or earthy appearance.

5. Alternating calculi, consisting of alternate layers of two or more primary deposits.

Anatomical Characters. In structure, a urinary calculus usually consists of a *central nucleus*, surrounded by the *body*, and outside of all there may be a phosphatic *crust*. The nucleus may or may not be of the same material as the rest of the stone, sometimes being a foreign body, mucus, or blood.

A section generally shows a *stratified* arrangement, or it may be partly or completely *radiated*.

Symptoms. The clinical signs of renal calculi are those consequent on the results of their presence, to wit: renal hemorrhage, renal congestion, inflammation terminating in abscess, pyelitis or pyelo-nephritis, cystitis, or renal colic.

The symptoms of renal colic begin abruptly, by severe, agonizing pain in the lumbar region following the ureters into the corresponding groin and thigh. Pain and retraction of corresponding testicle also of glans penis. Face pale and features pinched, the surface cold and damp. Irritability of the bladder, the urine passing in drops containing some blood. So severe is the pain at times that the patient may faint or pass into unconsciousness, or have a general convulsion. If both ureters are obstructed, uramic symptoms will arise.

The paroxysm usually terminates suddenly after some minutes or hours, the stone escaping into the bladder.

Prognosis. Renal calculus is attended with many dangers. It may produce extensive disorganization of the kidneys, or its passage along the ureter may prove fatal. If the stone be very large, or if more than one, the prognosis is graver. Calculus is a disease very apt to recur. Renal sand (gravel) and small concretions may, after more or less delay, be voided with the urine.

Treatment. An attack of *renal colic* is best relieved by a hypodermic injection of *morphina* and *atropina*, and a warm bath or a suppository of *ext. opii*, gr. j, *ext. belladonnæ alco.*, gr. ss, repeated if needed.

For attacks of gravel, liquor potassii citratis, f3ss, every three hours, and, if much vesical irritability, adding tinct. opii camph., f3ss-j.

For renal hemorrhage, Prof. Bartholow reports success with

R. Extracti ergotæ fluidi,

Tincturæ krameriæ, ää f 🖁 ij. M.

SiG.— 3 j every two or more hours.

I have always successfully controlled renal hemorrhages with twenty-grain doses of alumen, repeated p. r. n.

For uric acid calculi, as a solvent, Buffalo Lithia Springs water or the Rockbridge Alum Springs water of Virginia, or potassii tartraborates, "obtained by heating together four parts of cream of tartar, one part of boracic acid, and ten parts of water. A scruple may be given three or four times a day, in water, largely diluted."

For phosphalic calculi, as a solvent, ammonii benzoas, well diluted and long continued.

CVSTITIS.

Synonym. Catarrh of the bladder.

Definition. An inflammation of the mucous membrane lining the urinary bladder, acute or chronic in its course, and of either a catarrhal, croupous, or diphtheritic character; characterized by rigors, moderate fever, hypogastric pain, frequent but scanty micturition, and severe vesical tenesmus, the urine containing pus (pyuria).

Causes. Acute variety: long retention of urine; foreign bodies in the bladder; pyelitis; urethritis; blows over the pubes; myelitis, and secondary to fevers or diphtheria. Chronic variety: following the acute variety; retention the result of enlarged prostate or an urethral stricture; calculi; gout; chronic Bright's disease.

Pathological Anatomy. In acute catarrhal cystitis, there first ensues hyperæmia of the mucous membrane of the entire or a portion of the bladder, manifested by redness, swelling, and ædema; followed by an increased secretion of the small glands at the base of the bladder, and an increased growth and consequent desquamation of the vesical epithelium, together with a copious generation of young cells; if the hyperæmia be decided, rupture of the capillaries and extravasation of blood occur.

If the inflammation be intense, suppuration of the submucous connective tissue may result, and ulceration of the mucous membrane permit the submucous abscesses to empty into the bladder.

permit the submucous abscesses to empty into the bladder.

If the inflammation be of a croupous or diphtheritic character, the morbid anatomy does not differ from the same variety of inflammations in other mucous membranes.

In *chronic cystitis* "the mucous membrane is thick, blue-gray in color, and very tough. Muco-pus and viscid mucus are formed in large quantities upon its surface. The muscular wall of the bladder may sometimes be half an inch thick, and the fasciculi give a ribbed

appearance to the internal surface, called the "columnar bladder." The hypertrophy of chronic cystitis may be eccentric or concentric. In some cases diverticuli are formed, in whose walls are dilated and tortuous veins. In nearly all cases bacteria are found in abundance." (Loomis.)

Symptoms. Acute cystitis; the onset is usually abrupt, by rigors, slight fever, loss of appetite, sleeplessness, a feeling of depression; frequent micturition, though the urine is only voided drop by drop, and its passage followed by distressing vesical tenesmus, the result of spasm of the bladder; pain over the pubis and in the iliac regions, of a dull character, at times becoming sharp and agonizing. Burning along the urethra adds to the distress of the patient.

The urine is cloudy, of an alkaline reaction, and at times is fætid, the microscope showing epithelium, pus, and red blood corpuscles.

Chronic cystitis; the onset is gradual and insidious, and is excited by some obstacle to the evacuation of the urine, such as stricture, the presence of a stone in the bladder, or enlargement of the prostate gland. There are present dull pain, frequent but scanty micturition. The urine is alkaline, containing large amounts of muco-pus or pus; on standing, it deposits a thick, glairy, viscid sediment, in which, under the microscope, triple phosphates and large pus corpuscles, extremely regular both in contents and in shape, may be detected.

Although the quantity of urine voided by the patient is small, yet if immediately after micturition the catheter is used, several ounces of fætid, cloudy, alkaline urine may be removed.

Patients with chronic cystitis usually present decided constitutional debility and mental depression.

Severe local pain, emaciation, and occasional bloody urine indicate ulceration of the vesical mucous membrane.

Diagnosis. *Pyelitis* has lumbar pains following the course of the ureters, frequent micturition without the severe vesical tenesmus; the urine, although cloudy, has an acid or neutral reaction.

Prognosis. The *acute variety* is, as a rule, good, being controlled by the cause.

The chronic variety continues for years, and after hypertrophy of the bladder is incurable.

Treatment. Rest in bed is invaluable. The diet must be restricted, all highly-seasoned articles being particularly interdicted; milk is the most suitable article.

Warm applications over the pubic region are of benefit, and leeching and cupping over the bladder are of service.

The urine should be well diluted by large draughts of pure water, and particularly the alkaline mineral waters, to wit: Farmville lithia, Buffalo lithia, Rockbridge alum, or Vichy waters. The following formulæ are of decided benefit:—

	-	Acidi benzoici, Sodii borat.,	М.
Or—	₿.	Tinct. hyoscyami., fg vj	
		Tinct. opii camph., f \bar{g} vj Potassii bromidi.,	
		Sodii bicarb.,	
	Sic	Liq. potassii citrat., q. s. f \(\frac{7}{3} \) viij —Tablespoonful every two or three hours, in water.	M
Αv	alua	ble prescription is:—	
	Ŗ	Ext. pichi fld f \(\) j	
		Potassii nitrat	
		Elix. simplicis	M.
	SIG.	—One teaspoonful every two hours, well diluted.	

For the pain and tenesmus relief is afforded by a suppository of extractum opii and extractum belladonnæ, repeated as needed.

The vesical tenesmus is often benefited by extractum cannabis indica fluidum, 13ss, every three or four hours.

Chronic cystitis. The bladder should be completely emptied with the catheter several times in the twenty-four hours.

The use of eucalyptol, gtt. x-xv, every four hours, well diluted, or a good preparation of tar, or extractum grindeliæ fluidum, mxx-f3j, three or four times daily, or oleum santali, gtt. v-x, in emulsion or capsule after meals, are valuable remedies. Acidum boricum, gt. v-xv internally, has removed pus from the urine in chronic cystitis. Washing out the bladder with the following mixture is of decided benefit:—

K. Sodii borat.,	
Glycerini,	
Aquæ,	
Sig 13 ss-iss added to warm water and injected into the blad	law anda
or twice daily.	der once

The diet should be nutritious, but without spices of any kind. The free use of the alkaline mineral waters is of value.

MOVABLE KIDNEY.

Synonyms. Floating kidney; wandering kidney; ectopia renis. Definition. A condition of the kidney, either congenital or acquired, in which the tissues around about the organ are so lax and the renal vessels so elongated as to permit the kidney to be moved in certain directions, causing a movable tumor in the abdomen.

Causes. The kidney is normally held in position by the layer of peritoneum which is attached to the anterior surface of its adipose capsule. In movable kidney, the adipose tissue in which the normal kidney is imbedded partly or wholly disappears.

The renal vessels are in many cases abnormally long. Relaxation of the abdominal walls from pregnancy or other causes. The use of tight corsets or girdles about the waist; violence; increased weight of the organ from disease; the pressure of tumors growing in the neighborhood of the kidney; the traction of hernias.

The condition may be congenital or acquired, more frequently the latter. It is far more frequent in women than in men.

Symptoms. Floating kidney may and often does exist without any noticeable symptoms, the condition being unknown until accidentally discovered by the physician while making a physical examination of the abdomen.

As a rule, however, patients experience a heavy, dragging pain in the abdomen, aggravated when walking or standing. There are also present gastro intestinal symptoms, more or less constant, with melancholia, aggravated by the mental anxiety the presence of a *tumor* in the abdomen causes the patient, in spite of the assurances of the physician that it is not a cancer.

At times, from some unknown or unrecognized cause, the movable kidney swells and becomes very sensitive to the touch, and migrates a considerable distance from its normal position. Such an occurrence aggravates all the former symptoms mentioned. This condition has been ascribed to a twisting of the ureter and consequent retention of the urine in the pelvis of the kidney, or to a localized peritonitis, or to a partial strangulation of the kidney from compression or twisting of its blood-vessels.

Hysterical symptoms are frequently observed in women suffering from wandering kidney.

Diagnosis. The possibility of dislocation of the kidney is to be recollected in determining the nature of obscure tumors within the abdomen.

The late Prof. Austin Flint based the recognition of this variety of abdominal tumor on the following diagnostic points: "It is situated in the hypochondriac region. It has the size and shape of the normal kidney, and this may be determinable by palpation, which is most advantageously employed by placing one hand over the lumbar region and the other in front on the abdominal walls, and then making counter-pressure from one hand to the other. It is generally movable, and in some cases the organ can be restored to its proper situation."

Other tumors are to be excluded by the absence of their diagnostic characters.

Prognosis. It is a rare occurrence to have a fatal termination from movable kidney per se.

Treatment. Symptomatic. It is said that some of the inconvenience and sometimes suffering attending movable kidney may be lessened by means of an abdominal bandage, belt or supporter.

If attacks of pain and swelling occur, the patient should be placed in bed, have hot applications over the abdomen, and the use of opiates and attempts at replacing the organ.

Extirpation of a movable kidney has been successfully performed a number of times.

Nephrorraphy, an operation for fixation of the kidney by means of sutures, has been devised.

DISEASES OF THE BLOOD.

ANÆMIA.

Synonyms. Spanæmia; hydræmia.

Definition. A deficiency of red corpuscles in the blood, or of its more important constituents, such as albumin and hæmoglobin, or a reduction in the amount of blood as a whole; characterized by pallor and general weakness.

Oligamia is a general lessened amount of the blood. Ischamia is a localized anæmia.

Causes. Predisposing. Sex; females, pregnancy and menopause; heredity.

Exciting. Deficient food, air or sunshine; excessive work; mental worry; mental shock; prolonged and frequent nocturnal emissions; excessive nursing; chronic intestinal catarrh; Bright's disease; malaria; syphilis; cancer.

Pathological Anatomy. Post-mortem, the tissues are thin, shrunken and bloodless. If the anæmia has been of long duration, patches of fatty change are seen in the various organs. The blood has a brighter color, the result of diminution in the number of red corpuscles and the quantity of the hæmoglobin; it is thinner than normal, and coagulates slowly and imperfectly, from diminution of the fibrino-plastic constituent.

In health the blood of an adult contains about five million red corpuscles to the cubic millimeter (the female adult about half a million less). The white cells, in health, average about ten thousand to the cubic millimeter.

Symptoms. Pallor, gums, tongue, ear and conjunctivæ pale. Muscular weakness, inability for exertion. Deficient appetite and impaired digestion, attacks of vomiting the result of anamia of the medulla oblongata. Quickened respiration, irritable temper, vertigo in the erect position, attacks of swooning, hysteria, and rarely epilepsy. Irritable heart, with soft systolic basic murmurs. Nocturnal emissions in male and deficient menses in female. Marasmus in children. More or less general wdema of the eyelids and ankles. Long continued, symptoms of fatty changes in various organs, or gastric ulcer result.

Diagnosis. The symptoms of anæmia are so characteristic that an error is impossible; the cause of it, however, may be hidden.

Prognosis. Favorable if treated early. If protracted, results in more or less general symptoms of fatty degenerations or ulcer of the stomach.

Treatment. Remove the cause. Easily assimilated, blood-producing diet. Fresh air, sunlight and exercise short of fatigue. The anæmic patient should spend several hours in bed during the day-time. Purgatives, with stomachic tonics, to promote digestion.

For the anæmia proper, ferrum in some form is the most valuable remedy, always remembering that it is not assimilated if the intestines

and liver be torpid. The albuminate of iron is a favorite form for anæmia with weak stomach.

The following alterative tonic, known as Smith's (Dr. A. H.) "four chlorides," is frequently of value:—

R.	'Hydrargyri chloridi corrosivi, gr. j-ij	
	Liq. arsenici chloridi, f3j	
	Tinct, ferri chloridi, Acidi hydrochlorici dil., āā f 3 iv	
	Syrupi,	
	Aquæ, ad	M.

Sig.—One dessertspoonful in a wineglassful of water after each meal.

Cases of anæmia with weak stomach can take the following "iron lemonade" with ease:—

R	Tinct. ferri chloridi,							٠.	fgj	
	Acid. phosphor. dil.,								fʒij	
	Syr. limonis,								f Z iss	
	Aquæ,								f 🖁 ij.	M.
STO	One teaspoonful well	1.	4:1:	110	Ь				_	

SIG —One teaspoonful well diluted.

CHLOROSIS.

Synonyms. Essential anæmia; green sickness.

Definition. A pronounced anæmia met with chiefly in young girls about the age of puberty, characterized by diminution in the percentage of hæmoglobin.

Causes. The true cause unknown. A disease for the most part of puberty. Most frequently seen in the ill-fed, over-worked town girls, who are deprived of sunshine and fresh air. Heredity is supposed to play a part in its causation. Hammond maintains "that it is an affection of the nervous system, the blood changes being secondary."

Pathological Anatomy. Death from chlorosis is such a rare occurrence that little data is known. Virchow pointed out the hypoplasia of the arterial system, many arteries being congenitally small. The body is usually well nourished and the subcutaneous fat well distributed. There is pallor of the organs and muscular system. The spleen, lymphatics and the marrow of the bones are not affected.

Symptoms. The condition is associated with disorders of men-

struation. The young girl experiences a change of disposition, becoming morose and despondent, rarely, hysterical, or melancholiac.

"As respects the actual condition of the sexual organs, there are two forms of derangement which happen in chlorosis; there are the amenorrhæic form and the menorrhæic form."

After an attack of menorrhagia or after the failure of the flow to appear, the changes occur. The complexion changes, blondes becoming pallid, waxy and puffy without ædema; brunettes becoming muddy and grayish in color, with bluish-black rings under the eyes. Weariness and fatigue upon the least exertion; the heart irritable, with shortness of breath, pulse full but soft, and at times pulsations in the peripheral veins. The appetite is vitiated, the digestion imperfect; attacks of gastralgia are frequent.

A not infrequent complication is *gastric ulcer*. Phthisis develops in those having the slightest predisposition.

Examination of the blood shows a relative decrease in quality and quantity of the hæmoglobin, resulting in the blood being paler than normal. The red-corpuscles are also lighter in color and show less tendency to form rouleaux: their character also changes, not all being of uniform size, some normal, others small (microcytes), others unusually large (macrocytes), others irregularly shaped (poikilocytes). The number may be normal, 5,000,000 to the cubic millimeter, or the number is occasionally increased, but it is usually lessened, there being as few as 3,000,000 or 2,000,000.

The white-corpuscles are usually normal in number, but in some instances their number is increased (leucocytosis). Rarely granular bodies are found in the blood which are generally regarded as the products of the degeneration of the white blood-corpuscles.

Diagnosis. The disease is usually recognized at once by the color of the patient whence its common name, green sickness.

The circulatory symptoms and slight ædema may be mistaken for cardiac or nephritic diseases.

Prognosis. The liability to complications and also to relapses, and the lack of knowledge of the true cause, makes the prognosis always uncertain.

Treatment. Three indications to be met in the treatment of chlorosis, plenty of food, fresh air and ferrum. The form of iron is immaterial. The *tinctura ferri chloridi* is the preparation usually prescribed.

The following is Blaud's formula, so highly lauded by Niemeyer:--

Sig.—One to three or four pills three times daily.

In some instances ferrum alone does not seem to answer; in such cases the addition of arsenicum is valuable; a good combination is—

Sig.—After meals.

PROGRESSIVE PERNICIOUS ANÆMIA.

Synonyms. Idiopathic anæmia; anæmatosis; essential anæmia; anæmia of fatty heart.

Definition. A pernicious, progressive form of anæmia, of unknown cause, usually resisting all treatment, and toward its termination associated with fever.

Causes. The underlying cause of idiopathic anæmia is not known. Among the exciting causes may be mentioned, pregnancy, syphilis and great worry.

Pathological Anatomy. The blood is scanty and pale, with diminished red corpuscles, and hæmoglobin, showing a very feeble tendency to coagulate. There is no increase in the white corpuscles.

The *marrow* in adult bones becomes fœtal, red and adenoid, and contains microcytes; several other changes have occurred secondarily in the marrow.

Secondary to the anæmia, the heart, larger arteries and certain capillary tracts exhibit circumscribed or diffused fatty degeneration.

The liver, spleen, kidneys and stomach are decidedly anæmic, causing fatty changes in those organs. The skin may contain

petechiæ of a purplish or brownish tint, and internal hemorrhages are not infrequent; retinal hemorrhage is rarely wanting.

There is not much emaciation, though the pallor is pronounced.

Symptoms. It begins insidiously, with increasing languor and pallor, the muscular weakness compelling the patient to take his bed. Cardiac palpitation, dyspnæa, attacks of syncope, ædema and swelling about the ankles, with petechial spots scattered irregularly over the surface; tenderness over the sternum and other superficial bones is a frequent symptom.

The appetite is wanting, and nausea and vomiting occur, associated with marked *dyspepsia* and persistent *diarrhæa*. As the disease progresses a remittent form of *fever* develops, the temperature frequently showing 102–104° F.

Disorders of vision are the result of the retinal hemorrhage. The cardiac sounds are feeble and associated with soft basic or anæmic murmurs

The *blood* shows under the microscope the changes described in chlorosis, save the red corpuscles may be reduced to as few as 500,000 to the cubic millimeter.

Diagnosis. Progressive pernicious anæmia is distinguished from simple anæmia and chlorosis by the greater severity of the former. From leucocythemia by the normal-sized spleen and liver, and the absence of increase in the white corpuscles.

Prognosis. Unfavorable as a rule, although recoveries occur, but relapses frequent.

Treatment. The employment of arsenicum either alone or combined with ferrum has considerably changed the prognosis of pernicious anæmia. The arsenicum must be pushed to the extreme point of toleration and continued for a long time.

Rest in bed and a liberal nutritious diet are also essential.

LEUCOCYTHEMIA.

Synonyms. Leucæmia; white cell blood; white blood; anæmia splenica.

Definition. A condition in which there is an enormous increase in the number of white blood corpuscles, with enlargement of the lymphatic glands, spleen, and often of the bone marrow; viz.:

splenic, lymphatic, or myelogenic, and is characterized by symptoms of pronounced anæmia.

Causes. The real cause and nature of the affection is unknown. Pathological Anatomy. The spleen is increased in size, density and firmness; the lymphatic glands all over the body also enlarge, but are soft to the touch, often fluctuating; the marrow of the bones changes from its normal rose color to that of a greenish-yellow; the liver also enlarges enormously. The blood is paler than normal, its specific gravity reduced from 1.055 to 1.040 or lower, and the white corpuscles increased in number and in size, the red corpuscles being lessened in number and size.

Symptoms. The onset is insidious and the early progress of the disease is identical with that of simple anæmia, accompanied by swelling of the abdomen and a feeling of fullness and pain in the splenic region, due to the enlargement of that organ.

In the *lymphatic variety*, enlargement of the glands in the groin, neck, and axillary region are associated with the *great pallor*.

In the *myelogenic variety*, the bones, more particularly the ribs and sternum, are tender on pressure, the patient developing a waxy appearance.

In each variety the appetite is poor, the digestion feeble, the bowels loose, the patient easily fatigued, with cardiac palpitation, and dyspnæa, with ædema of the eyelids and ankles. The urine is scanty and of high specific gravity—1.020-1.030. Fatal hemorrhages occur near the termination of the disease.

The *blood* is pale and watery. The white blood corpuscles are enormously increased in number. The average number of white corpuscles to the cubic millimetre normally is about 10,000. Cases are recorded in which the number of white blood corpuscles has equaled or even exceeded the red blood corpuscles. The size of the white corpuscles varies in different cases and also in the same case.

The red blood corpuscles are frequently decreased in number and size.

Diagnosis. This should cause but little trouble if enlarged spleen, lymphatic glands and tender bones are associated with great pallor, and the characteristic appearance of the blood as demonstrated by a "puncture of the finger of the patient and receiving the blood on a piece of white linen or a lawn handkerchief, and placing by the side of it a similar stain of blood from a healthy subject. The full

color of the latter contrasts strikingly with the stain of the former, which is hardly of a blood color and translucent."

Prognosis. Unfavorable. The average duration is between two and three years. Cases of what are termed "Acute leucæmia," proving fatal in a few months, occur.

Treatment. Symptomatic. A combination of the following remedies with generous diet, fresh air, sunshine, pleasant surroundings, oleum morrhuæ and the hypophosphites have at times seemed of temporary utility, to wit: quinina, arsenicum, ferrum and ergota.

HODGKIN'S DISEASE.

Synonyms. Pseudo-leukemia; Pseudo-leucocythæmia; lymphatic anæmia; lymphadenoma.

Definition. An affection characterized by hypertrophy of the lymphatic glands in various parts of the body, associated with marked anæmia.

Cause. Unknown.

Pathological Anatomy. A hyperplasia of the lymph glands interfering more or less with their functions. The enlargement may be confined to one isolated gland or a number may be affected in different portions of the body, or a number in one location may be simultaneously affected causing a tumor varying in size from an egg to an orange or even a cocoanut.

The spleen and liver are involved in two-thirds of the cases. "The marrow of the long bones may be converted into a rich lymphoid tissue" (Osler).

The red blood corpuscles are decreased in number and altered in size and shape; the white blood corpuscles are often increased in number.

Symptoms. A slowly developing anæmia with isolated or diffused enlargement of the lymphatic glands. As the condition develops, fever of a remittent character occurs, with feeble cardiac action and shortness of breath. Hemorrhages may occur. The patient grows progressively worse with all the associated symptoms of deficient blood, death occurring by asthenia.

Diagnosis. A study of the clinical history will prevent error, as tubercular or scrofulous glands are accompanied with tubercular changes in the lungs, and do not present the same blood-changes as Hodgkin's disease.

Prognosis. Unfavorable. The progress may be slow, but it is none the less toward a fatal termination.

Treatment. The indications are all toward a building up of the blood. Amongst the remedies recommended are arsenicum, phosphorus ferrum, quinina, and oleum morrhuæ. Excision of the glands in the early stage may be practiced.

ADDISON'S DISEASE.

Synonym. Melasma supra-renalis.

Definition. "The bronzed-skin disease." Thus defined by Averbeck: "A well-marked constitutional disease, exhibiting itself locally as a chronic inflammation of the supra-renal capsules, but in its essence consisting in a peculiar anæmic condition, always tending toward death, which is characterized by intense development of pigment in the cells of the rete malpighii and in the epithelium of the mucous membrane of the mouth."

Causes. Obscure. Tubercle, scrofula, and syphilis have each been given as the cause.

Pathological Anatomy. A low form of inflammation, terminating in degeneration of the supra-renal capsule. The blood is deficient in fibrin and red corpuscles, with a slight increase of the white corpuscles. Fatty degeneration of the heart and vessels has been observed in some cases.

"The most striking change during life—the abnormal pigmentation—is due to the deposition of granular pigment in the cells of the rete malpighii, in the papillary portion of the cutis, and even in the connective tissue corpuscles. No change occurs in the proper structure of the skin. Similar pigment deposits occur in the mucous membrane of the mouth, especially along the edges of the teeth."

"The disease of the supra-renal capsules excites an irritation of the vaso-motor system—the trophic system—which leads to the pigmentation."

Symptoms. The onset of the disease is insidious, with a feeling of extreme languar, muscular fatigue, asthenia, indigestion, anorexia, dyspnwa, cardiac palpitation, vertigo, melancholia, and excessive drowsiness.

The surface is first pale, then changes to a hue like that of *melan-emia*, changing to *icteroid*, finally resembling the color of a mulatto, and then to a *lustreless bronze*. These changes also occur on the mucous membrane of the lips, tongue, gums, and mouth.

Prognosis. An incurable disease. Duration, a year or two. Treatment. Symptomatic.

HÆMOPHILIA.

Synonyms. Hemorrhagic diathesis; "bleeder's disease."

Definition. A congenital condition characterized by a tendency to uncontrollable hemorrhages, with or without abrasions.

Cause. Hereditary.

Symptoms. The bleeding appears about the period of first dentition, and consists of spontaneous hemorrhages from the mucous membrane of the nose, mouth, lungs, stomach, intestines, and genitourinary passages, or in perfect cases hemorrhages occur directly from the fingers, toes, lobes of the ears, back of the hands or arms, without any apparent change in the skin, and continue in spite of the most powerful means, for days or weeks. Traumatic hemorrhages occur if an injury of any kind is sustained about the period of the development of the bleeding.

Epistaxis is the most common form of all those named.

Attacks of arthritis with fever, occur with hæmophilia, resembling acute rheumatism.

As a result of the great loss of blood, the subject suffers from all the symptoms of profound anæmia.

Diagnosis. It is impossible to confound the "bleeder's disease" with any other affection.

Prognosis. Death is the usual termination within a few weeks from the time of its development, which may not be until adult life.

Treatment. Entirely symptomatic. It is claimed that "polassii chloras—an ounce of a saturated solution three times a day—combined with tinctura ferri chloridi," will eradicate the constitutional tendency.

SCORBUTUS.

Synonym. Scurvy.

Definition. A peculiar condition of malnutrition or antemia, gradually developing upon a dietary deficient in fresh vegetable material; characterized by decided anæmia, debility, mental lethargy, petechiæ, and a swollen and spongy state of the gums, with a tendency to bleed upon the slightest irritation.

Causes. The disease only occurs when fresh vegetable nutriment or some appropriate substitute has been for a time partially or com-

pletely withheld. It is held that the diet alone is not sufficient to cause the disease, the mental factor of depression of spirits, or in some cases home-sickness (nostalgia) must be associated.

It is sometimes classed as an infectious disease, due to a peculiar germ, a view which is gaining ground.

Pathological Anatomy. An undetermined derangement in the composition of the blood, with diminished proportion of the potash salts. Spleen enlarged. The tissues are wasted and present extravasations, due to either one of or the combined presence of the following conditions, to wit: liquid condition of the blood, allowing it to escape from the vessels, alterations in the walls of the vessels, or a vaso-motor paralysis.

Symptoms. General weakness, lassitude, indisposition to either mental or physical exertion. The skin is dry, rough, and of a muddy pallor, the face pale and bloated. Swelling and sponginess of the gums, with great tendency to bleed and an exceedingly offensive breath. Looseness of the teeth, hemorrhages from mucous surfaces, and extravasations of blood within and beneath the skin. The lips are pale, which is in striking contrast to the redness of the gums; the eyes are sunken and surrounded by dark blue circles.

Hemorrhages occur from the stomach, mouth, bronchial tubes, intestinal canal and vagina. The skin is dry and rough, resembling that of a plucked fowl. Œdema of the face and ankles not infrequent.

Depression of the spirits is characteristic. Palpitation and dyspnœa on exertion. Urine high colored, speedily becoming fœtid.

The patient usually longs for fresh vegetables and fruits.

Complications. Dysentery. Scorbutic dysentery is a frequent complication. It may co-exist with typhoid and typhus fever.

Prognosis. Favorable, if early and properly treated.

Treatment. The chief indication is the assimilation of the alimentary principles needed for the healthy constitution of the blood and the invigoration of the system.

The juice of lemons, oranges, and other fruits; it is wonderful what improvement will follow the use of two or three lemons daily. Antiscorbutic vegetables, to wit: raw cabbage, cresses and raw potatoes, in conjunction with meats, milk and farinaceous food.

Improve the appetite and digestion by the use of strychnina, quinina, mineral acids and bitter infusions. Potassii chloras, locally, will relieve the oral symptoms.

PURPURA.

Synonyms. Hæmorrhæa petechialis; Morbus maculosus Werlhofii.

Definition. An acute disease, characterized by purplish discolorations of the skin, the result of hemorrhages into the upper layers of the cutis and beneath the epidermis. When the purpuric spots are tiny, like a pin-point, they are termed petechiæ; when larger in size they are termed ecchymoses.

Varieties. Purpura simplex; purpura hæmerrhagica; purpura urticans; peliosis rheumatica.

Causes. Not properly understood, a special germ supposed to be the cause. It may occur at any age, but is especially frequent in children and elderly people. Its occurrence after the ingestion of certain articles of diet has been observed.

Symptoms. Purpura simplex is the mildest form of the affection, and is characterized by the sudden appearance of small, bright red spots—a cutaneous hemorrhage—most commonly on the legs, associated with slight lassitude, mild febrile reaction, and aching pains in the limbs. The hue of the spots rapidly fades to a purplish color and slowly disappears. Relapses are common.

Purpura hamorrhagica has in addition to the eruption of purpura simplex—the cutaneous hemorrhage—a flow of blood from the free surface of mucous membranes. The most common hemorrhage is epistaxis, slight or profuse. Other hemorrhages are hamatemesis, melana, hamaturia, hamoptysis, menorrhagia, and also into the substance of the mucous membranes of the palate, check, and gums. This variety is associated with great debility and depression, moderate fever and disorders of digestion. Marked anamia results from the hemorrhages.

Purpura urticans is a combination of urticaria and purpura simplex. It is characterized by rounded and reddish elevations of the cuticle, resembling wheals, but which are not accompanied, like the wheals of urticaria, by any sensation of itching or tingling. They are usually seated on the legs, thighs, breast, and arms, and are interspersed with petechiæ. They gradually form and subside within twenty-four or thirty-six hours. Relapses are frequent.

This variety is also associated with malaise, moderate fever, and pains in the limbs.

Peliosis rheumatica (Schönlein's Disease) is characterized by multiple arthritis and a purpuric eruption; frequently the arthritic symptoms are associated with urticaria or with erythema exudativum. Edema is often marked, as is the fever, sore-throat and general constitutional symptoms. The eruption is sometimes of vesicles—pemphigoid purpura.

Diagnosis. The purpuric eruption in each variety of the affection is so characteristic that an error seems impossible.

Prognosis. Purpura simplex and purpura urticans are favorable, but relapses are very frequent. Purpura hæmorrhagica is always a grave disease, often proving fatal from exhaustion, or more rarely, from cerebral or pulmonary hemorrhage. Peliosis rheumatica is often a severe affection, but recovery is the rule.

Treatment. Rest and a concentrated nutritious diet, and the moderate use of stimulants and tonics. *Arsenicum* in large doses is often valuable, using it in the form of *liquor potassii arsenitis*, to combat the resulting anæmia.

The internal use of *oleum terebinthinæ* is one of the most reliable remedies for all forms of the disease. The following is an eligible formula:—

R .	Ol. terebinthinæ,						
	Ol. amygdalæ express.,						
	Tinct. opii deodorat., .						
	Mucil. acaciæ,						
	Aq. laurocerasi,			. a	d.	٠	. f Z iij.

Sig.—One tablespoonful every three or four hours.

Among the other numerous remedies suggested, the most reliable have been acidum sulphuricum dilutum and tinctura ferri chloridi. Good results have followed acidum carbolicum, gtt. ij-iij every three hours, in cases seen by the author, and a particularly persistent case was cured by full doses of potassii iodidum.

M.

"If hemorrhages that are threatened come on with a strong pulse, flushed face, headache and excitement, digitalis, quinina, and ergota are the approximate medicaments" (Bartholow.)

Argenti nitras, gr. $\frac{1}{12}$ - $\frac{1}{4}$, three or four times daily is of value in purpura hæmorrhagica. Argentum is said to have a specific influence on the capillary circulation by its impression on the vaso-motor nerves.

Locally, to arrest bleeding, astringents and either hot or cold water or ice.

ACUTE GENERAL DISEASES.

PAROTIDITIS.

Synonyms. Parotitis; mumps.

Definition. An acute specific *infectious* inflammation of one or both parotid and other salivary glands and the surrounding connective tissue, with a very strong tendency to migrate into the mammæ or testes; characterized by pain, swelling and disordered function of the glands.

Causes. A specific poison. Contagious. Occurs in epidemics, although isolated cases are seen. Males more liable than females. The most common ages between five years and puberty. As a rule, it occurs but once in the same individual.

The period of incubation is from two to three weeks.

Pathological Anatomy. There is inflammation of one or both parotid glands, and in severe epidemics the cellular tissue pervading the gland is involved.

The catarrhal inflammation begins in the gland ducts and rapidly extends to the gland proper. There is congestion, swelling, and an infiltration of serous fluid, with more or less infiltration of the adjacent tissues. The swelling may suddenly reach an enormous size and as suddenly decline, the gland returning to its normal condition, or, rarely, an abscess results, with partial or complete destruction of the gland. Occasionally the submaxillary gland is involved, also the mammæ and testes.

Metastatic parotiditis occurs secondary to severe blood poisoning, as in pyæmia, typhoid or typhus fevers, or diphtheria. The usual termination of secondary parotiditis is by suppuration and destruction of gland structure.

Symptoms. The onset is rather sudden, by malaise, chill, fever, 101°-103° F., quick pulse, headache, dry skin, scanty urine, followed within a day or two by stiffness at the angles of the jaw, swelling of the parotid and other salivary glands, pain, increased by moving the jaws, with general wdema of the affected side of the face, at times the skin being reddened. Salivation is frequent, and occasionally deafness occurs.

The swelling and other glandular symptoms subside about the sixth or seventh day, to be followed by restoration to health, or, what is more common, the involvement of the opposite gland.

At any time during the disease *metastasis* to the *mammæ*, *ovaries* or *testes* is apt to occur, when the symptoms peculiar to such affections will be added. It has been noted that a *continuance* of the *temperature* after the decline of the parotid symptoms has begun, usually is significant of *metastasis*. It is claimed that the involvement of other organs during the course of mumps is not an example of metastasis, but is a true transfer of the disease.

Diagnosis. An error seems impossible.

Prognosis. Simple mumps, favorable; the chief danger being from the altered function of the mammæ, ovary or testes after metastasis.

Treatment. The disease being self-limited, the indications are entirely symptomatic, with attention to the secretions, although extractum pilocarpi fluidum, mx-xxx, repeated, has been used with varying success as a specific.

Locally, either cold or warmth to the affected gland, which ever is most agreeable, or equal parts of unguentum belladonnæ et hydrargyri.

If the swelling shows a tendency to linger, use small blisters over the part and administer *potassii iodidum*; if suppuration occur, evacuate pus, apply poultices and administer *quinina*.

If orchitis occur, the use of the *belladonna* and *mercurial ointment* or the *ice bag* to the inflamed testicle, and the internal use of *tinctura pulsatilla* gtt. iij—v every hour or two, or *potassii iodidum*.

DIPHTHERIA.

Synonyms. Putrid sore throat; malignant ulcerous sore throat; malignant quinsy; membranous angina.

Definition. An acute, specific, constitutional disease, both epidemic and contagious, beginning by an affection of the throat, characterized by a local exudation and glandular enlargements; attended with fever, great prostration of the vital powers and albuminuria, and having for its sequelæ various paralyses.

Causes. A specific germ, the Klebs-Læffler bacillus. It is preeminently a disease of childhood. It is apt to recur in those who have once been affected. All conditions of bad hygiene increase its virulence and diffusion, although the chief cause of its spread is contagion.

The poison exists in the exudation and secretions of the fauces and saliva, but not in the breath, and floats in the atmosphere at a considerable distance from the patient. The virus adheres to the clothing, the bedding, the furniture, and the room which the patient occupied.

The period of incubation is from three to five days.

Pathological Anatomy. The diphtheritic inflammation differs from either the croupous or catarrhal form, in that the exudation is not only upon, but also within, the substance of the mucous membrane.

At first there is *redness*, which may begin in any part of the throat, associated with *swelling* and an *increased secretion* of viscid mucus. The redness spreads over the entire mucous surface, when the *exudation* makes its appearance. The deposit may commence from one or several points, such as one tonsil, the soft palate, or the back of the fauces, which, however, speedily extend and coalesce, forming extensive patches, or cover uniformly the entire surface.

The patches are of variable thickness, which is increased by successive layers being formed underneath.

The *color* is usually gray, white, or slightly yellow, but may be brownish or blackish, the *consistence* ranging from "cream to wash leather."

On removing the membrane, which is accomplished with more or less difficulty, a raw bleeding surface is exposed, and at times an ulcer, which is speedily covered with a fresh deposit.

If the exudation separate itself, it is either not renewed at all or only in thinner films.

The exudation or membrane, examined by the microscope, is composed of fibrin, pus corpuscles, epithelial granular cells, and the Klebs-Læffler bacillus and other pathogenic bacteria.

If the *larynx*, *trachea*, or *nasal* mucous membranes participate in the disease, the *croupous* and not the *diphtheritic* form of inflammation occurs.

The *lymphatic glands* of the neck, whose vessels originate in the faucial tissues, are enlarged and inflamed, and contain large numbers of *bacteria*, probably originating as the result of decomposition.

The muscular tissue of the *heart* becomes soft, is easily torn, and its fibrillæ are far advanced in granular degeneration. Ulcerative endocarditis has been frequently observed.

The kidneys undergo a granular degeneration in severe attacks.

The blood undergoes alteration, being black and fluid.

Symptoms. Following the law of *contagious* diseases, the symptoms vary in intensity in different cases, the prominent symptoms being often disproportionate to the gravity of the attack.

The invasion may be mild, with rigors succeeded by moderate fever, headache, languor, loss of appetite, stiffness of the neck, tenderness about the angles of the jaw, or slight soreness of the throat.

In other cases the *invasion* is more *abrupt* and *severe*, with *chilliness* followed by great *febrile* reaction, 103° to 105° F., *pain in the ear*, *aching of the limbs*, *loss of strength*, *painful deglutition* and *swelling of the neck*, compelling the patient to take to bed from the onset.

The appetite is poor, the tongue slightly coated, sometimes more or less exudation appearing upon it, the bowels being either regular or slightly relaxed. The pulse, at first full and strong, soon becomes either rapid or slow, but compressible. The urine is scanty, high colored and contains albumin.

The local symptoms in the majority of cases are associated with the throat. The patient complains of a frequent and persistent desire to hawk, in order to clear the throat. On inspection the fauces are seen red and swollen and more or less covered with the diphtheritic exudation; sometimes the tonsils and uvula are greatly swollen and spotted with exudation. In severe cases, more or less ulceration or sloughing may be observed. Not infrequently fragments of exudation, the false membrane, are expectorated, with particles of the ulcerated tissues, having an offensive odor, which is transmitted to the breath. The lymphatic glands of the neck are enlarged and tender, and in severe cases the tissues of the neck are greatly tumefied.

Extension to the *nasal cavities* causes a *sanious* and *offensive* discharge from the nose, with attacks of *epistaxis*.

Extension to the *larynx* is indicated by *hoarseness* or *complete loss* of *voice*, *croupy cough* and obstructive *dyspnwa*, which often becomes urgent, the breathing being *noisy* and *stridulous*, and subject to paroxysmal exacerbations. If the inflammation extend to the *bronchi*, the breathing becomes still more embarrassed.

Duration. Ranges from two to fourteen days, an average being about nine days, although complications and sequelæ may prolong its course.

Relapses are not uncommon.

Sequelæ. Those who recover from a severe attack remain often for weeks with a *pale* and *cachectic* appearance, due to the profound blood alteration.

Paralysis is a common sequela, following the mild as often as the severe attacks. Usually not occurring until the patient seems fully convalescent.

Pharyngeal paralysis is the most common, causing difficulty or inability of deglutition, fluids regurgitating through the nose.

Cardiac paralysis, bradycardia, is not infrequent, the pulsations descending to 60, 50, 40, and in a case seen by the author, to 20 per minute. Heart failure and fatal syncope may occur at any time during the disease.

Diphtheritic paralysis may affect the motor muscles of the eye, causing strabismus; the muscles of one side, hemiplegia; of the legs, paraplegia; and of the bladder, leading to retention of urine or difficulty in voiding it.

Multiple neuritis with the attending loss of power is a rare sequela. Sensation is also diminished in the paralyzed parts.

Diagnosis. From follicular ulceration of the tonsils, which is frequently termed diphtheria, by the slight or absent systemic symptoms, the ulcerated condition being limited to the tonsils, but often one, and the absence of glandular enlargement and following palsies.

From *pharyngitis*, by the absence of exudation and loss of faucial tissue and constitutional symptoms.

From *scarlatina*, by the presence of the eruption and the absence of membrane in the fauces. The association of scarlatina and diphtheria must not be forgotten.

From membranous croup, by the difference in the constitutional symptoms; croup appears sporadically and is not contagious, diphtheria being highly contagious and frequently occurs in epidemics; in diphtheria of the larynx, the depression is clearly that of bloodpoisoning, while in croup, the depression is in proportion to the mechanical obstruction of the respiration by the membranous exudation. The pathology of croup is simple and easy of investigation; diphtheria is obscure in its etiology and progress. The temperature

record of croup is a high one until carbonic acid poisoning is imminent from the mechanical obstruction to respiration, while in diphtheria, the tendency to a decline in the temperature after the fourth day is nearly characteristic, regardless of the amount of laryngeal obstruction. In croup the pharynx contains no membrane, and is but slightly, if at all, inflamed, and associated trouble in the nose is of the rarest occurrence, the very reverse obtaining in diphtheria. In croup the laryngeal symptoms are from the onset, while in laryngeal diphtheria the pharyngeal symptoms almost always precede. In croup glandular involvement is a clinical novelty, as are subsequent palsies, while glandular involvement and various palsies are the rule in diphtheria. Albuminuria is the rule in diphtheria, seldom occurring in croup.

Prognosis. Always grave, but more so in children than in adults. Its gravity, in the majority of cases, is proportionate to the local symptoms. The average mortality is about ten per cent.

Favorable indications are, moderate fever, strength slightly impaired, a good constitution, and moderate exudation.

Unfavorable indications are, high fever, great depression, spreading exudation, great swelling of the cervical glands, large amount of albumin, extension to larynx and nasal mucous membranes, hemorrhages from the fauces and nose, and an epidemic character.

Treatment. No specific plan of medication has been found uniformly successful. It is a disease of debility. The blood being more or less altered, it follows that sustaining measures should be resorted to in all cases.

That the real character of diphtheria is often misunderstood, may be inferred from a perusal of the medical periodicals of the day, it being proclaimed by a number of writers that in widespread epidemics of this most dangerous and fatal malady they had employed remedies so valuable that they had not lost a patient.

The *diet* should be of the most nutritious character from the onset, with such articles as milk, eggs, broths, and oysters, at *intervals* of every *two or three hours*. If deglutition be too painful, resort must be had to nutritious *enemata*, the following being a suitable formula:—

R.	Milk,		٠									fãj	
	Spts. f												
	Egg,	٠	٠	٠	۰	٠	۰				٠	One.	M.

Sig.-Little salt added, beaten up and warmed.

Stimulants should be used boldly from the onset, guiding the dose by the effect; usually, a child of two years requires from thirty to sixty minims of spiritus vini gallici or spiritus frumenti, every two or three hours; an adult from two to four drachms every three hours. It is a mistake to wait for signs of debility before using alcohol in diphtheria.

Of drugs, two are warmly advocated: Ferrum and Hydrargyrum. Of the great value of tinctura ferri chloridi there is no question; but for hydrargyri chloridum corrosivum, it has hardly realized the expectations of the profession, except in laryngeal cases. A combination of ferrum and potassii chloras, in full doses, frequently repeated, have seemed, when begun early in the attack, to modify the course of the malady, and they have the additional advantage of acting locally upon the throat as they are swallowed. A good formula is—

R.	Tinct. ferri chlor	r.,							gtt. v-x-xx	
	Potassii chlor.,								gr. iij-v	
	Glycerini,								f 3 ss	
	Syr. zingib., .			۰	ad				fʒj–ij	Μ.
~	_		- 4				 9.3		.1	

Sig.—In water every three hours, for a child of two or three years.

Ferrum and hydrargyri chloridum corrosivum, repeated every second or third hour, may be combined as follows:—

R.	Hydrargyri							
	Tinct. ferri	chloridi	,				m_v−x	
	Glycerini,						mχ	
	Aquæ, .			 ad			f3j.	Μ.
Sig	-Every hou							

The efficacy of the above are greatly enhanced by the addition to each dose of tinctura belladonnæ, gtt. j-v.

Quinina, gr. xvj-xxiv per day for a young adult, and gr. v-x for a child, should be used throughout the disease; if irritability of the stomach prevent its administration by the mouth, it can be used as a suppository, or locally in the form of the oleate.

Calomel in small doses, combined with sodii bicarbonas every hour until the breath becomes fatid, is beneficial, and especially in cases showing a tendency to spread toward the larynx. Indeed, a tolerance to calomel seems to exist in diphtheria of the larynx.

Pilocarpus has been recommended in diphtheria. I do not consider it a safe remedy in the majority of cases of this disease.

Watch the urine carefully throughout the disease; diminution in the amount is of bad prognosis.

Isolation of the patient and disinfection of the clothing and utensils is of importance. All clothing should be soaked twenty-four hours and boiled in a two per cent. solution of carbolic acid.

Inhalations of steam and hot water, and allowing the patient to suck pellets of ice, give relief. Sponges dipped in hot water and applied to the angles of the jaw are beneficial.

The chief danger of communication of the poison is the air exhaled from the fauces and from the surface. Dr. J. Lewis Smith recommends the following plan to counteract this danger. Add four ounces of the following solution to one quart of water and allow them to simmer constantly, near the patient, in a broad surfaced tin or zinc wash basin: R. olei eucalypt., acidi carbolici, āā fʒj, terebinthinæ, ʒviij. M. The vapor is strong, penetrating and prophylactic, but not unpleasant. In hot weather, or when fire is not convenient, saturate cloths a foot square with the same solution and place them on paper on the bed of the patient.

Locally. Two indications to be met, one to prevent or limit the local development of the bacilli, and the other to combat the effects of the toxic material which the bacilli produce. The first question asked is, can we dissolve the membrane? "In laboratory, yes, in throat, no" (Da Costa).

Cleanliness of the fauces is of the utmost importance, and if a non-irritating disinfectant be added, its value is enhanced. Prof. Bartholow "has seen excellent results from the frequent application of a solution of acidum lacticum, strong enough to taste sour, by means of a mop." Much good is reported from spraying the throat with a fifty per cent. solution of hydrogen peroxide. Swabbing the throat with the following is valuable:—

R	Acidi carbolici,					. m.xx	
	Tincturæ ferri chlor.,					. fgiv	
	Glycerini,						
	Aq. destil.,					. f 🖁 j	M.
SIC	I ocally every three he	011110	,			0 -	

Sig.—Locally every three hours.

Applications of corrosive sublimate to the throat are often valuable. Dr. Ernest Laplace has demonstrated that corrosive sublimate in solution slightly acidulated with tartaric acid, has its germicide property increased, as in the following 1–500 solution (R. Hydrargyri chlor. corrosiv. gr. 3,85; acid tartaric, gr. 19,25, M.).

The following, used as a gargle, or applied by a mop, is useful:-

R.	Potass. chlorat,								
	Acid. carbol., .	٠			٠		٠	gr. ij–iv	
	Tinct. myrrh, .								
	Inf. cinchonæ, .							fīj.	M.

Or-

I think it a mistake to struggle with children over their refusal to use a gargle or allow the use of the spray, as they don't know how to gargle and they are afraid of the spray. Much better to add plenty of glycerin to their medicine, and use no liquid for some time after swallowing the dose.

For laryngeal diphtheria the same general treatment, especially the mercurial, with inhalations of lime by slacking freshly-burned lime in a vessel and directing the vapor to the child by a newspaper, or some similar contrivance, or using three parts of liquor calcis and one part of glycerin, in an atomizer, every half hour or hour, or liquor trypsin, as a spray. If these means fail, resort must be had to tracheotomy, or intubation of the larynx, which have succeeded in many desperate cases.

For nasal diphtheria, the same general treatment, and syringing the nose every two or three hours with a weak solution potassii chloras, or acidum carbolicum, or hydrogen peroxide, or the following:—

R .	Sodii sulphit.,								
	Glycerini,								
	Aquæ,							f Ziv.	Μ.

For the paralysis, strychnina and ferrum internally, or strychnina hypodermically, with the galvanic or faradic current locally.

ACUTE ARTICULAR RHEUMATISM.

Synonyms. Rheumatic fever; inflammatory rheumatism.

Definition. A constitutional disease, characterized by fever, inflammation in and around the joints, occurring in succession, and a great tendency to inflammation of either the endocardium or pericardium.

Causes. The *predisposing* causes are inherited tendency, scarlatina, and the puerperal state.

The *exciting* causes are exposure to cold and chilling of the body. Rheumatism rarely occurs before seven or after fifty years. The liability to the disease is increased by having had an attack.

Pathological Anatomy. The blood contains an excess of lactic acid. The joints bear the brunt of the attack; the synovial membrane is reddened, the vascularity of the synovial fringes is increased, so with the synovial fluid, which is thinner, of a reddish color, containing some gelatinous coagula of fibrin, and under the microscope nucleated cells, ordinary pus cells being rarely seen.

The swelling visible about the affected part depends mostly on inflammatory cedema of the connective tissue around the joint.

The pain is probably due, in all cases, to stretching of and pressure on the elements of the tissues by the dilated capillaries and the inflammatory œdema. For the changes which ensue when the endo- and pericardium are attacked, the reader is referred to the sections on those diseases.

Symptoms. Begins suddenly, generally at night, with a chill or chilliness, pain and stiffness in the joints, loss of appetite, at times, nausea and vomiting, followed by fever, the temperature soon reaching 102° F., to 104°, in rare cases 108° to 110° (the hyperpyrexia), the pulse seldom exceeding 95, great thirst, profuse acid sweats, scanty, high colored, acid urine, at times showing traces of albumin, the bowels constipated. The fever continues throughout the attack, showing marked remissions. Delirium is absent, except the hyperpyrexia occur. Sleep is prevented by the pain and the profuse perspirations. The strength is moderately well preserved.

The skin is often covered with an eruption of miliaria rubra, red papules and miliaria alba, the result of irritation at the orifices of the sweat glands, from the excessive perspiration.

The local phenomena are pain, tenderness, increased heat, swelling and redness of one or more joints; if but one joint, it is termed monoarthritis, if more than one, polyarthritis. Pain is aggravated by motion and pressure. Swelling is most apparent in those joints not covered with muscle, to wit: knee, wrist, elbow, ankle, and the hands and feet, and is proportionate to the acuteness of the attack.

The inflammation may abruptly cease at one or more joints, and as suddenly attack others.

The disease is extremely irregular as regards the number of joints affected, although the local manifestations are controlled by an important pathological law, to wit: the law of parallelism. Corresponding joints are often affected together, and when not, the different affected joints are either on one side of the body or those on both sides which are analogous, as the knee, elbow, wrist, ankle, hip, and shoulder, are attacked together.

Complications. Pericarditis, endocarditis, myocarditis, cerebral endarteritis, bronchitis, pneumonitis and pleuritis.

Duration. The duration of acute rheumatism is governed entirely by the presence or absence of complications. Uncomplicated cases recover in from *thirteen* to *twenty-one* days, although they may be prolonged to five or six weeks. Relapses are frequent.

Diagnosis. A typical case cannot be mistaken for any other disease, but cases running a *subacute* course may be mistaken for acute rheumatoid arthritis, gonorrhœal rheumatism, or pyæmia.

Acute rheumatoid arthritis attacks one joint at a time and becomes permanent, has slight if any fever, no sweats or cardiac lesions.

Gonorrheal rheumatism is associated with a gleety discharge, or follows the sudden cessation of an acute or subacute gonorrheal discharge, attacks either the ankle or wrist only, is slowly influenced by treatment, and lacks the febrile phenomena.

Pyæmia is usually manifested at a single joint at the time, and is followed by suppuration and all the symptoms of hectic fever.

Prognosis. Recovery is the rule in uncomplicated cases, the mortality being about three per cent. When death occurs it usually depends upon hyperpyrexia, cardiac complication, or cerebral endarteritis.

Treatment. Owing to our imperfect knowledge of the exact nature of this most painful disease, its treatment still remains either empirical or is directed toward certain prominent symptoms or complications. Garrod claims that "colored water" is about as potent as anything else, for it is, he says, a "self-limited disease," sometimes running a long and sometimes a short course.

Rest in bed, whether the pain forces it or not, is important. Warmth is as imperative, for which purpose the patient should be kept in blankets—no sheets—and wear woolen garments. The diet should be easily digested food, milk being the most suitable.

Strong and vigorous patients do well with acidum salicylicum or the salicylates in large and frequently repeated doses.

R.	Acidi salicylici,											
	Liq. ammonii acetat.,									٠	fziv	
	Spts. ætheris nitrosi, .											
	Syr. simplicis,			۰							f 3 j.	M.
Sig.	-Tablespoonful every t	hre	ee	ho	urs	s, ·	wel	1	dil	ut	ed.	

Or-

Sig.—Dessertspoonful every three or four hours, till relief, when widen interval.

If benefit follows, the evidence is quickly afforded in the relief of pain and the decline of the temperature and swelling. If, therefore, after three or four days' use of the salicylates or acidum salicylicum, as above recommended, signs of improvement are wanting, the treatment had better be changed for the alkaline treatment, which consists in the administration of an ounce and a half of the alkaline carbonates, either alone or with a vegetable acid, each twenty-four hours, until the urine becomes neutral or alkaline, when the quantity is reduced to an amount sufficient to maintain alkaline urine.

The following are good formulæ for the alkaline treatment:-

Dissolve in a glass of water and drink effervescing, every three hours.

		Aquæ font., .				٠						٠	٠	. fǯij. M
	SIG	-Tablespoonful	ev	er	y 1	hr	ee	or	fo	ur	h	oui	rs.	

Dr. S. Solis-Cohen has reported good results from the following combination, in anæmic and run down cases, to which he has given the name of mistura ferro-salicylata:—

R.	Sodii salicylatis,	
	Liq. ammonii citratis, B. P., f z ijss	
	Acidi citrici, gr. x	
	Olei gaultheriæ, m xxxij	
	Glycerini, q. s. ad f 3 iijss	
M	isce adde lente,	
	Tinct. ferri chloridi, f z iv.	M.
Sig.	-One or two teaspoonsful every two, three, or four hours.	

Prof. DaCosta reports a lessened proportion of cardiac complications with ammonii bromidum, gr. xy-xx, every four hours. I much

cations with ammonii bromidum, gr. xv-xx, every four hours. I much prefer ammonii salicylas, gr. x-xv, in simple syrup, well diluted, every four or six hours.

Subacute attacks and lingering cases are favorably influenced by cinchonidinæ salicylas, or—

R. Lithii salicylatis, gr. xv-xx

		A lauroceresi											M.
		Aq. laurocerasi,		۰	٠		۰	•		•		13].	IVI .
	Ever	y four hours.											
Or-	_												
	B .	Potassii iodidi,										P iv	
		Sodii salicylatis,				۰					٠	3 iv	
		Elix. cinchonæ,			٠							f Z iss	
		Infus. gentianæ,	,	0	٠			4				f Z iss	

Good results are reported from the use of salol, gr. v-x, every four hours, from ammonii hydrochloras, gr. xv-xx, every four hours, and from salipyrin, in solution, every four hours. (R. Salipyrin, 3iij; glycerini, f3iij; syr. aurantii, f3vj; aquæ destil., ad f3vj. M. SIG.—Tablespoonful, well diluted).

Whichever plan, acidum salicylicum, salicylates, alkaline or ferrum, is adopted, *quinina*, gr. xij-xx, per day, should also be used.

Pain and restlessness should be controlled by opium in some form, in full doses, or atropina, gr. $\frac{1}{30}$, hypodermically.

For the hyperpyrexia, quinina, gr. xxx-lx, repeated p. r. n., with the cold bath or wet back.

Locally, the affected joints should be wrapped in cotton-wool or flannel, saturated with a solution of tinctura opii, one part, and liq. piumb. subacetat. dil., two parts, or olei gaultheriæ, f3j, with lin. saponis comp. f3iii, or—

R.	Sodii bicarbonatis,						ξij	
	Tinct. opii,						f 3 ss	
	Aquæ bul.,						Oij.	M.

Dr. Bartholow finds the application of *blisters* an effective method. He says: "I have small blisters, the size of a silver dollar, placed around the joint, leaving an interval between for succeeding applications. It is by no means so painful and disagreeable as it appears at first sight. The blisters remarkably relieve the pain, bring about a more alkaline condition of the blood, and render the urine less acid, or bring it to neutral, or even to alkaline."

The complications are to be treated according to their character.

MUSCULAR RHEUMATISM.

Synonyms. According to location, to wit: cephalodynia; lumbago; torticollis; pleurodynia.

Definition. An affection of the voluntary muscles, inflammatory in character, either *acute* or *chronic*; characterized by pain, tenderness, and stiffness of the affected muscles. It is never complicated with cardiac disease.

Causes. A disease of adult life. One attack predisposes to another. Almost always due to cold or damp, or direct draught of cold air. Gout increases the tendency to attacks.

Pathological Anatomy. The true nature of muscular rheumatism is not yet determined. Virchow suggests a "hyperæmia of, and scanty serous exudation between, the muscular striæ, and in chronic cases inflammatory proliferation of the connective tissue."

Symptoms. The *first* attack is generally *acute*. Onset rather sudden, with *pain* in the affected muscles, with slight *tenderness*, and considerable *stiffness* and *difficulty of movement*, by which also the pain is increased.

The suffering may be severe and constant, or only on motion. *Spasm* of the affected muscles may occur. *Objective* symptoms are wanting, except it is evident that the patient keeps the affected muscles as quiet as possible. Fever is absent. The pain may prevent sleep.

Duration, acute form, about one week. Chronic returns frequently, and finally becomes constant and aggravated when the weather is damp.

Varieties. It may affect any or all of the voluntary muscles, but its most frequent and important varieties are:—

1. Cephalodynia. Situated in the occipito-frontal muscles. Distinguished from neuralgia of the trifacial, or occipital nerve, by pain on both sides of the head, excited or aggravated by the movements of the muscle and by absence of disseminated points of tenderness.

The muscles of the eye may be affected, and movements of that organ excite pain. If the temporal and masseter muscles are attacked, mastication excites pain.

- 2. Torticollis. Wry neck, or stiff neck. Situated in the sternomastoid muscles. Generally limited to one side of the neck, toward which side the head is twisted, great pain being excited on attempting to turn to the opposite side. Rheumatism of the muscles of the back of the neck, cervicodynia, may be mistaken for occipital neuralgia.
- 3. Pleurodynia. Situated in the thoracic muscles, and may be mistaken for pleuritis, or intercostal neuralgia, from which it is differentiated by the absence of the diagnostic features of each. Pain is excited by forced breathing, coughing and sneezing.
- 4. Lumbodynia or lumbago. Situated in the mass of muscles and fasciæ which occupy the lumbar region. Most common variety. Usually affects both sides. It may set in rapidly and become very severe. Motion of any kind aggravates the pain, often becoming very sharp or stabbing in character. It is sometimes complicated with acute sciatica, when the suffering is agonizing.

Diagnosis. The different varieties may be mistaken for any of the following ailments, to wit: trifacial, occipital or intercostal neuralgia, pains of progressive muscular atrophy, neuritis, syphilis, metallic poisons, or painful affections of the loins, arising from calculi or gravel in the kidney.

A careful examination of the history is usually sufficient to arrive at a correct diagnosis.

Prognosis. Difficult to eradicate, and in chronic cases to ameliorate, but is not dangerous to life. Death never results.

Treatment. *Rest* is the first indication. This is accomplished in *pleurodynia* by firmly strapping the affected side with broad strips of plaster, extending from mid-spine to mid-sternum.

The *local* application to the affected muscles of *hot* poultices, made of two-thirds *pilocarpus* leaves, and one-third *flaxseed* meal, changing them every two hours, is the most rapidly successful treatment in acute cases.

Internally antipyrin, gr. x-xx, repeated in several hours, or ammonii hydrochloras, gr. xv-xx, every three hours, or sodii salicylas, gr. xv-xx, every two or three hours, are each of value. Prof. Bartholow declares that lithii bromidum is almost a specific in muscular rheumatism.

For the pain, and consequent sleeplessness, use-

R. Pulv. ipecae et opii, gr. x
Potass. nitrat, gr. v-x. M.
SIG.—In powder, morning and night.

Or, hypodermically, at the seat of pain, *morphina*, gr. $\frac{1}{80}$, p. r. n.

The following liniment is valuable in many cases:-

R.	Quininæ sulph., .											gr. xl	
	Ol. gaultheriæ, .		٠						۰			fZj	
	Lin. saponis co.,												M.
Sig.	-Thoroughly appli	ied	l s	eve	era	l t	im	es	a	da	у.		

In attacks where the disease is limited to a few muscles, the following liniment is valuable:—

R. Chloral hydrat., Camphoræ, M. et adde		,			āā		٠	3 ss	
Lanolin, Sig.—Apply locally.	۰		۰					ξj.	M.

In all forms, but more particularly in lumbago, a few dry cups over the seat of the pain give immediate relief.

Chronic cases: Rest, flannel worn next to the skin, stimulating and anodyne liniments, mild galvanism, dry heat, as ironing over the affected part with a common flat iron, a piece of paper or towel being placed next to the skin.

Internally, potassii iodidum, ammonii hydrochloras, sulphur, guaiacum or arsenicum variously combined.

RHEUMATOID ARTHRITIS.

Synonyms. Arthritis deformans; rheumatic gout.

Definition. An inflammation of the joints, accompanied with but slight fever, without suppuration; progressive in character, causing nearly symmetrical enlargement and deformity of various articulations.

Causes. More common in females than in males, and in the weak and anæmic. Among the causes are bad hygiene, exposure, prolonged lactation, frequent pregnancies, menopause, grief, tuber-cular diathesis, and following attacks of articular rheumatism.

Pathological Anatomy. It is not rheumatism, as the blood contains no *lactic acid*. It is not gout, as *uric acid* is not found in the blood nor *urate of sodium* in the joints.

At first rheumatoid arthritis is attended with hyperæmia of the affected synovial membrane and increase of the synovial fluid. Soon the capsular ligament becomes irregularly thickened, the synovial fluid decreasing. If the process continue, the internal ligament is destroyed, thus allowing dislocation to occur. The inter-articular fibro-cartilages ulcerate and disappear, as do the cartilages covering the ends of the bones, the ends of the bones becoming smooth and eburnated, and often greatly enlarged.

Symptoms. Either acute or chronic, the latter most common.

Acute form involves several joints at the same time, and is attended with slight pyrexia.

Chronic form slowly involves one joint, which seemingly soon recovers, and is attacked again, and may never recover, but grows progressively worse.

The joint slowly enlarges, is painful, movement exciting neuralgic pains along the limb. Soon the articulation becomes rigid or slightly movable after prolonged attempts. Redness and tenderness are wanting. Crepitation is distinct after ulceration has destroyed the cartilage.

The hands are first involved, the disease spreading symmetrically from articulation to articulation, until in severe cases every joint is deformed.

Diagnosis. Chronic articular rheumatism is often confounded with rheumatoid arthritis; but the former lacks the marked structural changes and the progressive involvement of joint after joint.

Gout differs from rheumatoid arthritis by the presence of deposits of urate of sodium in the joints, the ears, tips of fingers and the bursæ over the olecranon process of the elbow, the presence of uric acid in the blood, and the decided history of acute paroxysms.

Gonorrhwal rheumatism, so-called, has symptoms akin to rheumatoid arthritis, but the history of urethral suppuration clears up the diagnosis.

Paralysis agitans, when pronounced, might be confounded with rheumatoid arthritis, if the examination were limited to the joints; but the whole history, such as the tremor, the gait, etc., should prevent error.

Prognosis. If early treatment be instituted, the disease may be held in abeyance for several years. After pronounced structural changes have begun, the malady is incurable, although it may remain stationary for a long time.

Treatment. If treatment be instituted before serious structural leisons have occurred, the author has seen benefit in many cases by the following treatment: Oleum morrhuæ carefully and thoroughly rubbed into the affected joints three times a day, with the internal use of lithii citras effervescentes 3j, three times a day, and the following tonic mixture:—

Massæ ferri carbonat.,						
Liquor. potass. arsenit.,				۰	. m v	
Vini xerici,					. fʒj	
Aquæ,					. fʒj.	Μ.
 1 11 111 . 1						

After meals, well diluted.

Sodii salicylas is recommended early in the disease.

Complete recoveries are reported from the long-continued administration in small doses of *liquor potassii arsenitis*.

Attention to diet and hygiene are also necessary. When structural changes have destroyed portions of the joint, palliative treatment is the only indication.

GOUT.

Synonyms. Podagra, gout in the foot; chiragra, the hand; gonagra, the knee.

Definition. A constitutional disease, usually inherited; characterized by the sudden occurrence of a paroxysm of severe pain and

swelling in one of the smaller joints—the great toe usually—with the presence of uric acid in the blood, and the deposit of the urate of sodium in the structure of the joint.

Causes. *Predisposing*; inherited, male more than female—women after menopause.

Exciting; malt liquor and wine drinking; large consumption of animal food; lead poisoning; winter season.

When inherited tendency, may begin early in life; when acquired tendency, after thirty-five years.

The pathological cause consists in the presence of an excess of uric acid in the blood, in the form of urate of sodium.

Pathological Anatomy. Gout is characterized by the deposit of urate of sodium from the blood into the structure of joints and tissues that are not very vascular. The deposit is associated with signs of inflammation, to wit: hyperæmia, redness of the surface, with swelling and effusion in and around the affected joint. The surfaces of the joint are incrusted with chalk-like masses, consisting of urates, which become greater with each attack, finally causing great deformity.

The deposit usually begins in the metatarso-phalangeal joint of the great toe, but other and many joints are soon affected.

The deposits may also be found in the knuckles, eyelids, and cartilages of the ear.

"Crystals of urate of soda are deposited in the tubules and intratubular tissues" of the kidneys—"gouty kidney"—and may be seen by the naked eye, the kidneys becoming small, granular and fibrous.

Hypertrophy of the left ventricle and of the arteries, ending in atheromatous changes, are results of gout.

Symptoms. Acute gout is rare in the United States. It occurs in paroxysms; one year's interval between the first and second attack; six months usually between the second and third, after which it may occur at any time.

Prodromes usually precede the paroxysm for several days, to wit acid dyspepsia, constipation, headache and lassitude.

The paroxysm begins suddenly, between midnight and 2 A. M., with acute pain in the ball of the great toe, which becomes red, hot, swollen, and so sensitive that the slightest touch cannot be borne.

The veins are filled, the foot, ankle and leg swollen, and the limb

the seat of sudden spasmodic contractions, which increase the suffering; slight relief is afforded by elevating the limb. Associated with the local symptoms are chill, fever, quickened pulse, thirst, coated tongue, constipation, and scanty, acid, high colored urine, which deposits, on cooling, a heavy brick-dust sediment.

Towards daylight the symptoms ameliorate, to return again at sundown, the severity gradually lessening, until the fourth or fifth day, when convalescence is established, the patient, as a rule, feeling better than before the attack.

Chronic Gout. Either the result of acute attacks or with a greater number of joints being attacked.

The *paroxysms* occur at any time, but develop slowly, with less pronounced local and general symptoms. Deposits are noticed, the joints becoming hard, knobby, and often distorted. The deposits or *chalk-stones* (urate of sodium) occur about the joints, tendons and bursæ, and helix of the ear.

Diagnosis. An error cannot occur if the history of the case can be obtained, to wit: hereditary tendency, age, sex (females rare, until menopause), mode of living, character of symptoms, and presence of the characteristic deposits.

Prognosis. Acute gout rarely fatal; is prone to return, but much depending upon the mode of living.

Chronic gout decidedly shortens life. The most serious signs are those indicating advanced renal disease, with non-elimination of uric acid. Gout influences unfavorably the prognosis from acute diseases or injuries.

Treatment. For the acute paroxysms at once, vinum colchici radicis, gtt. xv-xx-xxx, every two hours, well diluted, either alone or in combination with a potassium salt, or sodii salicylas, gr. xx, every three or four hours, well diluted. While the acute symptoms of gout are not so rapidly relieved by sodii salicylas, as are those of acute rheumatism, still it is an invaluable remedy and is rapidly succeeding colchicum. After the decrease of the acute symptoms, lessen the dose, but continue the remedy for some time.

Dr. Bartholow recommends the following pill:-

В.	Colchicinæ, ".	٠	٠	٠		٠	٠	٠	0			gr.	1
	Ext. colocynth.	CC	m	٥.,			۰	۰		۰	٠	gr.	SS
	Quininæ sulph.,	٠		٠	٠							gr.	ių.

Every two or three hours.

For the pain, hypodermic injection of morphina, and wrapping the inflamed joint in cotton-wool saturated with liq. plumb. sub-acetat. dil. and tinctura opii.

The diet must be restricted to liquid food.

For subacute or lingering cases, and in chronic gout, potassii iodidum is valuable.

For chronic gout, regulated diet, free action on the secretions, and lithii citras effervescentes, 3j, three or four times a day, well diluted with water; and perhaps a course of quinina, ferrum and arsenicum.

To prevent paroxysm, keep secretions acting, by the free use of pure water or a good alkaline water, such as Buffalo lithia or Farmville lithia water, or Saratoga Vichy.

The diet is of the greatest importance, and should consist chiefly of vegetables and fruit, excepting tomatoes and strawberries; fresh meat may be used once a day, as may oysters, fish and soups. Alcoholic and malt liquors are contraindicated, as are tea and coffee; skimmed milk should replace all the above. No eggs or dishes containing eggs, no pastry, hot bread or cakes, no sweetmeats, spices or condiments.

Systematic exercise, especially walking, is of great advantage.

Cold bathing, with caution, while the vapor or Turkish bath are of benefit.

Changing from a cold to a warm climate in winter, and the use of flannel underclothing, are strongly recommended.

DIABETES MELLITUS.

Synonyms. Glycosuria; melituria.

Definition. A chronic affection characterized by the constant presence of grape sugar in the urine, an excessive urinary discharge, and the progressive loss of flesh and strength.

Causes. Most common in males. Occurs at all ages, but most frequently between twenty-five and fifty years. It is often hereditary. Disorders of the nervous, hepatic and renal systems. Excessive use of farinaceous food and malt liquors. Sexual excesses.

The exact pathology of diabetes mellitus differs in different cases, and in the present state of knowledge no exclusive view can be adopted. Still, there are reasons for believing that, in a large proportion of cases, the nervous system is primarily at fault, though the character of the lesions may differ.

Pathological Anatomy. None peculiar to diabetes are yet recognized.

Hyperæmia and hypertrophy of the liver and kidneys are generally present, the result of increased functional activity.

The changes in the lungs peculiar to phthisis are often found in very chronic cases.

The changes in the nervous system are not fully determined.

Symptoms. Clinically, cases differ greatly in their course and severity; one class presenting slight symptoms and a chronic course; another class having marked local and constitutional symptoms and running an acute course. The symptoms of a typical case may be arranged under the following heads:—

Urinary Organs and Urine. Micturition more frequent and the urine increased in quantity. Pain over the region of the kidneys.

The quantity of urine may amount to 4, 8, 12, 20 or 30 pints in twenty-four hours. It is usually pale, clear, and watery, having a sweetish taste and odor, the specific gravity ranging from 1.025 to 1.050. It ferments rapidly if kept in a warm place. It yields grape sugar to the usual tests, the amount present varying from an ounce to two pounds in the twenty-four hours.

The urea and uric acid are increased. Albumin may be present.

The increased passage of a large quantity of saccharine urine causes a constant itching, burning and uneasy sensation at the prepuce, along the urethra, and at the neck of the bladder; in females, itching and eczema of the vulva are common; in children, incontinence of urine is frequent.

Digestive Organs. An almost constant symptom is thirst, with a dry and parched condition of the mouth. At times the appetite is excessive, again absent. The breath may have a sweetish odor, the tongue irritable, red, and often cracked. Dyspeptic symptoms are common, and occasionally vomiting. The bowels are constipated, the stools pale and dry. At times diarrhea may occur.

The patient complains of feeling very weak, languid, and of sore-

ness and pain in the limbs; there is more or less emaciation, a harsh, dry skin, the countenance distressed and worn.

The mind is often greatly altered; depression of spirits, decline in firmness of character and moral tone, with irritability, are present. Sexual inclination and power are demolished. Defects of vision are present.

The blood and various secretions contain sugar.

Complications. Pulmonary phthisis; Brights' disease; defects of vision from atrophy of the retina or the formation of a soft cataract; boils and carbuncles, and chronic skin affections, such as psoriasis and eczema.

Course. The clinical history varies in different cases. In the majority of instances the course is chronic, lasting for years, the symptoms beginning insidiously, and becoming progressively worse, with, at times, decided remissions. Occasionally the disease runs an acute course, death occurring within four or five weeks.

Termination. The majority of cases ultimately prove fatal, the symptoms markedly changing, the *urine* and *sugar diminishing* in quantity, the occurrence of *albuminuria*, *disgust for food and drink*, and the development of hectic fever and a colliquative diarrhœa.

The fatal result usually arises from gradual exhaustion, from blood poisoning, leading to stupor, ending in complete coma, or occasionally to delirium or convulsions, or from complications.

Rarely death occurs suddenly from uramic convulsions or uramic coma.

Diagnosis. Diabetes mellitus only exists when *grape sugar* is permanently present in the urine. "It is not the quantity, but the persistence of sugar which constitutes diabetes."

When are present grape sugar in the urine, with more or less increase in the urinary flow, it can be mistaken for no other affection.

From *Bright's disease*, by the absence of dropsy, and of tube casts in the urine; the amount of albumin in the urine is never so great or constant in diabetes mellitus as in Bright's disease.

From *Diabetes insipidus*, by the absence of sugar in the blood and urine, and the larger quantity of urine voided in polyuria.

Simple glycosuria differs from diabetic glycosuria in that the amount of sugar in the urine is not constant—at one time being present, at another absent—the amount of urine voided is never in excess of health; simple glycosuria is a disease of the aged; diabetic glycosuria

usually appears under fifty years. Simple glycosuria often results from the inhalation of chloroform, the use of chloral, in the insane, from excitement, or as one of the results of injuries to the head.

Prognosis. Most unfavorable as regards a cure, it being fairly questionable if complete recovery has ever occurred in a typical case. Still, decided amelioration may take place in the symptoms, and the progress of the malady be greatly retarded. The younger the patient the more rapid the fatal termination.

Treatment. Impress upon patients the importance of a strictly regulated diet. Prohibit or restrict the consumption of such articles as contain sugar or starch, especially ordinary bread or flour, sugar, honey, potatoes, peas, beans, rice, arrowroot, cracked wheat, oatmeal, turnips, beets, corn and carrots, prunes, grapes, figs, bananas, pears, apples, and liquors of all kinds whether distilled or fermented.

The main diet should be of animal food, including meat, poultry, game and fish.

A moderate amount of fluids should be allowed, and in a majority of cases *milk* will prove beneficial, although, theoretically, contraindicated. Tea, coffee and cocoa, without sugar, may be allowed in moderation, *glycerin* or *saccharin* being used as a substitute for the sugar.

Regulated exercise is of importance. The patient should wear flannel, and have two or three warm baths every week, or an occasional Turkish bath.

Therapeutical Treatment. It is difficult to estimate justly the action of any drug in this disease, for, as is so well known, a proper modification of the diet will alone produce the most marked improvement.

Opium exercises an influence over the excretion of sugar, but the effect is not maintained in all cases. Pavy strongly urges the use of codeina in doses of gr. ½-iij, three times a day. The use of morphina hydrochloras, gr. j daily, or pulvis opii, gr. iij-v daily, is a favorite prescription. Prof. DaCosta suggests the use of ergota, which has decreased the urinary discharge and the quantity of sugar in a number of cases. Prof. Bartholow has met with an apparent cure by ammonii carbonas. Uranii nitras, gr. iij, three times daily, will often markedly reduce the urine and sugar, and sodii salicylas, gr. xv, three times daily, will markedly control the formation of sugar. Liquor. bromini arsenitis, mij-v, three times a day, often gives good results. Dickinson remarks that "strychnina is, of all remedies, the most

constantly useful." Potassii bromidum, 3j, during the twenty-four hours, is strongly urged. The following remedies are recommended by different observers, to wit: pepsinum, liquor potassii arsenitis, iodum, potassii iodidum, acidum lacticum, glycerinum, quinina, and tinctura cannabis indicæ. The evidence in favor of the majority of these drugs is far from satisfactory.

For diabetic coma, alkalies are particularly indicated. Sodium carbonas subcutaneously, or by intravenous injection, watching closely the effect on pulse and heart, as recommended by Stabelman. Use also inhalations of oxygen, and diuretics and fluids to promote elimination of toxic products.

Symptomatic treatment is mostly called for. For emaciation and anæmia, ferrum and oleum morrhuæ; for sleeplessness and restlessness, morphina, potassii bromidum, chloral, or hyoscinæ hydrobromas. For boils and carbuncles, calcii sulphidum. Duchenne suggests the following solution for the excessive thirst of diabetic patients:—

B. Potassii phosphat., two parts Aquæ, seventy-five parts.

Sig.— One teaspoonful twice or thrice daily in wine or hop tea.

The dyspepsia and lung symptoms must be managed on general principles.

The constant *galvanic current* has been productive of good results. A change of scene and air is beneficial.

Surgical operations should on no account be undertaken on diabetic patients.

DIABETES INSIPIDUS.

Synonyms. Polyuria; polydipsia.

Definition. An affection characterized by the habitual discharge of a very large quantity of pale, watery urine, free from albumin and sugar.

Causes. Occasionally hereditary, or diabetes mellitus may have existed in the parent; more common in children or young adults; men are more liable than women; injuries and diseases of the nervous system; exposure to cold; drinking freely of cold water; fatigue; prolonged debility; malaria; syphilis.

The probable immediate cause of the excessive flow of urine consists in dilatation of the renal vessels, the result of paralysis of their

muscular coat, caused by derangement of innervation, as the condition can be induced experimentally by irritating a spot in the fourth ventricle, or by section of portions of the sympathetic nerve.

Symptoms. The affection is characterized by great thirst, with an increased flow of pale, watery, slightly acid urine, the amount varying from one to five or six gallons in the twenty-four hours. The specific gravity ranges from 1.001-1.007. Sugar and albumin are absent. Urea and the other solids are increased. The appetite is voracious, the bowels are obstinately constipated, and the skin is dry and harsh.

The large flow of urine is usually preceded by various nervous phenomena, as nervousness, irritability, inability to concentrate the mind, vivid imagination, a failure of memory, and headache.

Unless the affection is soon arrested great loss of flesh and strength result.

Diagnosis. It differs from diabetes mellitus by the absence of grape sugar in the urine.

From paroxysmal diuresis, by the absence of the increased urine permanently.

From *interstitial nephritis*, by the greater amount of urinary discharge and the absence of albumin, ædema, and casts.

Prognosis. Rather unfavorable as to a radical cure, unless caused by syphilis. Death rarely is due to the diabetes, but to some intercurrent malady that the patient has been unable to withstand, on account of the weakness produced by the diabetes.

Treatment. If due to syphilis, potassii iodidum and hydrargyrum are of real benefit. Prof. DaCosta has had success with ergota in the form of the fluid extract or the aqueous extract. Pilocarpus has been used with success. Prof. Bartholow recommends galvanism in cases not cured by potassii iodidum, placing "one electrode to the neck below the occiput, the other to the hypochondriac region in turn." Valerian, potassii bromidum, and sodii salicylas have been used. The author has effected a cure in three cases, where other remedies had failed, by the use, internally, of—

R .	Strychninæ sulphatis,					gr. $\frac{1}{\sqrt{0}}$	
	Acid. hydrochlor. dil.,					mx	
	Aquæ laurocerasi,	٠				fgij.	M.
Well	l diluted.						

The obstinate constipation is best overcome by pilulæ catharticæ compositæ, one at bedtime.

LITHÆMIA.

Synonyms. Lithiasis; uric acid diathesis; half gout.

Definition. A condition in which the fluids of the body are saturated with nitrogenized waste, in the form of *lithic* or *uric acid*; characterized by marked dyspepsia, various nervous phenomena, muscular and articular pains, bronchial catarrh, all or any of these associated with scanty, high-colored, acid urine.

Causes. High living, with little exercise; imperfect digestion of nitrogenized food; impaired elimination of uric acid.

Pathology. Not yet clearly determined. The non-elimination of certain products which have a deleterious influence upon the nervous system. That uric acid does exist in the blood is now generally accepted.

Symptoms. Those of dyspepsia associated with irregular bowels, scanty, high-colored, acid urine, sp. gr. 1.024–1.028, containing neither sugar nor albumin, but showing an increased proportion of urates. Also depressed spirits, impaired memory, loss of interest in occupation, sleepless nights, attacks of vertigo, neuralgic pains in the head, and a constant dread of apoplexy or cerebral disease. Also pains in the joints, neuralgic in character.

If the condition be allowed to continue, the following organic changes may result, to wit: fatty heart; fibroid kidney; enlarged liver, or changes in the cerebral vessels.

Diagnosis. From gout, by the absence of acute paroxysms and resulting changes in the joints.

Prognosis. If properly recognized and treated, complete recovery will result, although it is a disorder of long duration.

If not properly treated, develops some one of the organic diseases mentioned.

Treatment. Regular diet, using fresh meat once daily, poultry, game (plainly cooked), fresh fish, oysters, occasionally eggs, lettuce, spinach, celery, cold slaw and tomatoes; avoid all kinds of starchy and saccharine foods, also all stimulants, tea and coffee, using milk, skimmed milk, or milk and cream. Act freely on all the secretions, particularly the liver and kidneys. Systematic exercise. Avoid tonics, bromides, chloral and opium. Long course of alkaline waters, particularly the lithia waters. Good results follow lithii citras, gr. xx, t.d., sodii phosphas, gr. xxx, ter die, or acidum benzoicum, gr. x, t.d.,

all well diluted with water. One of the very best drugs is acidum nitricum dilutum, gtt. x, in half a glass of water, four times a day, with the occasional use of pilulæ rhei compositæ at bedtime. Strontium has acted nicely in several cases.

R.	Strontii bromidi puræ,							
	Glycerini,							M.
Sic	Infus. gentianæ,			•	•	•	13 vj.	191.

CHOLERA.

Synonyms. Epidemic cholera; Asiatic cholera; malignant cholera; spasmodic cholera.

Definition. An acute, specific, infectious disease, epidemic in the majority of, although endemic in other, localities; characterized by the transudation of serum into the stomach and intestinal canal, and violent purging of a peculiar, rice-water-like fluid, the persistent vomiting of a similar material, severe muscular cramps, and a condition of prostration, followed by collapse and death, or of a reaction from the collapse and the development of the typhoid state (cholera typhoid).

Causes. A *specific poison*, the "comma bacillus" of Koch. Cholera is but feebly *contagious*, in the usual acceptation of that word, but it is unquestionably *infectious*.

The evidence seems conclusive that the *cholera stools* are the main, if not the only, channel of infection, and that the great cause of the propagation of cholera is the contamination, with the cholera stools, of the water used for drinking purposes. Milk may also be the vehicle by which it spreads. It is claimed that the bacillus is inert in the intestinal canal unless the individual is in the "receptive state—" that is a condition of intestinal catarrh, such as results from eating unripe fruit, beer and spirit drinking, and indigestible food. It is also determined that the bacilli are destroyed by acids, and that if the stomach be normal, cholera will not result. "With pure water, pure air, pure soil and pure habits, cholera need not be feared." (Hart.)

Little, if any, danger exists from being in the presence of the affected, although the emanations from the cholera excreta in the atmosphere may generate the disease if swallowed or inhaled. The dead bodies of cholera subjects apparently possess slight infective

property, "the bacteria of decomposition" probably destroying the cholera germs. One attack does not afford protection against another.

The period of incubation is short, under a week, usually.

Pathological Anatomy. This is, as yet, far from satisfactory. The morbid appearances in the majority of cases of death from cholera may be thus summarized. The temperature generally rises after death, the body remaining warm for a considerable time. Rigor mortis rapidly ensues, the muscular contractions being often so powerful as to displace and distort the limbs. The skin is mottled and the body greatly shrunken. The blood is darker in color, thick, viscid, feebly coagulable, and slightly acid. The arteries are quite empty of blood; the veins, on the other hand, are distended. The organs are, as a rule, pale and shrunken.

The stomach and intestinal mucous membranes are congested, and present evidence of extravasation and ecchymoses, or are bleached and pale. The stomach and intestines usually contain a quantity of whey-like material, having an alkaline reaction, as well as quantities of cast-off epithelium and the peculiar bacillus. It is thought by many that the stripping-off of the epithelium is a post-mortem phenomenon. The Peyer's solitary and Brunner's glands are usually enlarged and prominent, and occasionally evidences of ulceration are apparent in the solitary glands, and sections placed under the microscope show the "comma bacillus." The villi of the mucous membrane, as well as the epithelium of the small intestines, are stripped off, leaving the basement membrane, for the most part, exposed. The liver is more or less advanced in fatty degeneration, presenting a somewhat mottled, yellowish discoloration. The kidneys are congested, the epithelium of the tubules granular and detached from the basement membrane, blocking up the tubes. Prof. Bartholow observed, in all of his autopsies, "considerable hyperæmia and dilatation of the vessels of the medulla oblongata. The constancy of this lesion would seem to indicate a relationship between congestion of the medulla and the cramps."

Symptoms. In accordance with the law of epidemic infectious diseases, the onset, course and character of the symptoms vary in different cases and at different periods in the same epidemic.

The disease may either set in suddenly in a patient previously in good health, or it may follow an attack of rather severe and persistent

diarrhœa, with pain, nausea, vomiting and depression. Such cases are termed Cholerine, the stools of which are infectious.

In a typical case there are three stages: first, diarrhœa; second, prostration; third, collapse, or, in favorable cases, reaction.

First Stage. Begins with chilliness, excessive thirst, coated tongue, unpleasant taste in the mouth, slight abdominal pain, and three or four copious, watery, yet fæcal stools during the day, and a decided feeling of weakness, the stools rapidly becoming whey-like, easily voided, but with force and only slight pain.

Second Stage. The stools rapidly increase in number, are voided with a rushing force, and consist of many quarts of grayish, or whitish, rice-water-like fluid, accompanied with forcible vomiting, first of the contents of the stomach, mixed with more or less bilious matter, afterward of the peculiar rice-water-like material; thirst becomes most intense, increasing or diminishing with the variations in the number of the vomiting and stools; severe muscular cramps soon follow, most severe in the calves, although occurring in all parts of the body.

Third Stage. The stools, vomiting and cramps continue. The appearance of the patient becomes frightful; the eyes are sunken and surrounded by blackened rings, the nose pinched and pointed, the cheeks hollow, and the lips blue (facies cholerica); the surface cold and moistened with a sticky perspiration; the skin of the hands and fingers has the sodden appearance of the "washerwoman who has washed all day," and if picked up in folds, the fold but slowly disappears. The temperature rapidly falls, the pulse becomes small and compressible, barely perceptible at the wrist, and the heart beats are scarcely recognizable. The voice is weak, husky and sepulchral (vox cholerica), the tongue is like ice, the breath is cold and icy, the urine markedly diminished and albuminous. The mind is not cloudy, but most patients are apathetic and indifferent to their danger. This, the algid stage of cholera, or cholera asphyxia, usually terminates in death in from three to twelve, twenty-four or forty-eight hours, but reaction may be established.

Stage of Reaction. The temperature of the body rises, the pulse gradually becomes fuller and stronger, the countenance becomes brighter, the stools less frequent and more fæcal, the vomiting decreases, the thirst lessens, the urine increases in amount, but continues albuminous, the patient entering a slow convalescence, or

typhoid symptoms develop, the so-called cholera typhoid, which prolongs the recovery for several weeks.

Convalescence is often prolonged and complicated by the development of severe bed sores, boils, bronchitis, pneumonia or parotitis.

Sequelæ. Suppuration of the parotid gland; painful tetanic contraction of the flexor muscles of the limbs; abscesses or ulcers of the limbs; profuse sweats; roseola, erythema, urticaria, and rarely vesicular eruptions.

Diagnosis. The epidemic character, and rapid spreading, and great mortality of the affection prevents its being mistaken for any other disease, although isolated cases are often confounded with cholerine or with cholera morbus, the points of distinction being few, unless the "comma bacillus" only be found in the stools of true cholera.

Prognosis. Very unfavorable, the mortality ranging from twenty to eighty per cent. The last epidemic in this country was much milder than former ones. The prognosis is controlled by the general condition of the patient, the age, habits, and the development of the algid stage; the prognosis being more favorable in those cases which develop gradually than in those in which it reaches its acme at a single bound; the very young or very old, those addicted to the various excesses and surrounded by unfavorable hygienic conditions, are more apt to perish than are others.

Treatment. The success depends, to a great extent, upon its prompt and early treatment, for experience amply attests that the arrest of the disease in the diarrheal stage is comparatively easy, and that in the stage of collapse its cure by any means whatever is altogether an exceptional occurrence; therefore, during the prevalence of cholera the mildest cases of diarrhea ought to receive prompt treatment, for many cases have their beginning as a mild diarrhea.

It must not be overlooked that intelligent nursing and regimen are equally as important as medical treatment.

The patient should be put to bed at once, and all food withheld for a time at least. Small pellets of ice may be allowed instead of water.

"Of all the remedies proposed for the arrest of the diarrhoa, not one has done so much good as sulphuric acid. It is usual, and generally best, to combine some opium with it (R. Acid. sulphuric. aromat. f3v, tinct. opii deodorat. f3iij. M., S. Ten to twenty drops every hour or two in sufficient water)." (Bartholow.)

Large doses of bismuth should be of value in this early stage, but opium is particularly indicated, preferably in the form of morphia hypodermically. During the epidemics of 1892-93, good results were reported from the internal use of hydrogen peroxide, f 3 ij, with aqua destillata, f 3 viij, in cupful doses every two hours. Salol and plumbi acetas are of value for the early diarrhea.

Ziemssen says: "Calomel has the first place of all drugs which have been recommended in the prodromal stage. Begin with two or three doses of gr. vij, followed with small doses—gr. ¾—every two hours."

It is now generally admitted that as the first symptoms of cholera are those of intestinal catarrh, direct medication ought to be of the greatest service. This is done by *enteroclysis* or irrigation of the canal, with large amounts, from one to three gallons twice daily, of hot soaped water, hot four per cent. solutions of hydrogen peroxide, or weak solutions of tannin, or hot one per cent. solutions of common salt.

The enteroclysis is accomplished by means of a soft rubber tube, one metre in length and of suitable size to be introduced into the rectum, in front of the promontory of the sacrum, into and up through the sigmoid flexure and into the descending colon. This tube which is connected with a reservoir should not be too small nor too large, in order to facilitate its introduction through the folds of the sigmoid portion of the lower bowel.

In fact, the greatest difficulty to be encountered, is to successfully pass the tube in front of the promontory of the sacrum, and enter it into the sigmoid flexure. The tube should be of proper firmness to prevent it from bending or buckling upon itself when the end (which in all cases should be rounded) comes in contact with the obstructing folds of the intestine.

For the distressing vomiting, lavage of stomach with H₂O₂, f3ij (medicinal) to two or three pints of hot water, or *iced champagne*, cocaine, or acidum hydrocyanicum may sometimes give relief.

Locally, either continue the mustard application to the abdomen or the constant use of rubber bags filled with boiling water.

For the *cramps*, hot water in bottles, hot irons or bricks applied over painful parts, or an ointment of chloroform or chloral, chloroform or ether inhalations, or the use of the following hypodermic solution, strongly recommended by Prof. Bartholow (R. Chloral, 3ii),

morphinæ sulph., gr. iv, aq. laurocerasi, f3j. M. Sig.—Fifteen to thirty minims each injection.)

For the collapse, heat to the surface and the free use of *stimulants*, or *spiritus frumenti* or *spiritus vini gallici*, hypodermically, also the hot bath, also *hypodermatoclysis* and the intravenous injection of saline fluids and hypodermic injections of strychninæ sulphas., gr. $\frac{1}{20}$. *Heat* is of the greatest value in all stages of cholera, both externally as very hot baths (hot air or hot water), and hot rectal injections.

If reaction occur, treat indications as they arise, and use tonics, such as ferrum, quinina and arsenicum.

All the discharges from the patient should be thoroughly disinfected as soon as voided, and the stools and vomited material buried.

TRICHINOSIS.

Synonyms. Trichinæ; Trichina spiralis; "flesh-worm disease." Definition. A typhoid condition, the result of the entrance of a parasite—the *Trichina spiralis*—into the intestinal canal, and their subsequent migration into the muscular structure: characterized by severe gastro-intestinal irritation, severe muscular soreness, and a low typhoid condition.

Cause. The *Trichina spiralis* are introduced into the human body by eating the infected hog's flesh, either raw or but imperfectly cooked.

Description. The parasite is found in two forms, to wit: intestinal trichina, which is sexually mature, and muscle trichina, which is sexually immature.

The intestinal trichina is a small, hair-like worm, the male measuring $\frac{1}{18}$ of an inch, and the female $\frac{1}{28}$ of an inch in length; the head is smaller than the rest of the body; the tail of the male has a bi-lobed prominence, between the divisions of which the anal opening is placed, and from which a single spiculum can be protruded; the female has a blunt, rounded tail, the reproductive outlet being situated toward the anterior part of the body; the ova are very small, containing embryos being produced viviparously at the rate of at least one hundred each week after the entrance of the female into the intestinal canal.

The muscle trichina develops its sexual apparatus after it has entered the intestinal canal of the host.

The viable embryos discharged from the female are in a state of motion, and at once migrate from the intestines to the muscular structure of the individual, and here set up inflammatory action, they becoming surrounded by a capsule or shell in which they are coiled.

After a time, in the muscle, the *trichina* undergoes a further change; lime salts being deposited in and about the capsule and in the parasite itself, when minute specks of lime are seen distributed throughout the muscular structure.

The development of the parasite from the period of impregnation up to the time of sexual maturity is, under favorable conditions, less than three weeks. Within two days from the ingestion of the infected pork occurs the maturation of the muscle larvæ; in six days more the birth of embryos occur, and in about two weeks the migrating progeny have arrived at their habitat, the muscular structure.

Symptoms. These depend upon the number of parasites in the infected food. According to Dr. Sutton, of Indiana, a piece of pork the size of a cubic inch contained eighty thousand trichinæ. There are three stages described, to wit: the intestinal, the migration, and the encapsulation.

Intestinal stage, a gastro-intestinal inflammation, with nausea, vomiting, and watery diarrhæa, the severity depending upon the number of the parasites ingested.

Migration stage, a typhoid-like fever, rapid, feeble pulse, profuse sweats, intense thirst, dry tongue and lips, and red, swollen face, with soreness and tenderness of the muscular structure, increased by any muscular act. As a rule the mind is clear but decidedly apathetic.

Encapsulation Stage. If the number of parasites ingested have been few, recovery may occur in this stage, but if the number have been large, the gastro-enteritis, fever and muscular phenomena are severe, the patient is in a critical condition, between twenty and fifty per cent. succumbing.

Diagnosis. Unless the physician has some intimation of the cause, cases are readily mistaken for either ordinary ileo-colitis or typhoid fever.

Prognosis. Depends upon the number of trichinæ in the pork eaten. Mortality between twenty and fifty per cent.

Treatment. The preventive treatment consists in eating no pork that has not been so prepared as to kill any trichinæ that might exist. If the parasites have been recently taken, within the first four or five days, emetics and purgatives to remove them from the stomach and intestinal canal are indicated. After thorough action from these, attempts may be made to destroy such of the parasites as have escaped the action of the emetic or purgative. For this purpose much is said in favor of glycerini, one part, aquæ, two parts; or a trial can be made of acidum carbolicum and tinct. iodi, as suggested by Prof. Bartholow. Quinina gave the best results in the cases seen by Dr. Sutton.

After migration has begun, the powers of life should be sustained by nourishing food, stimulants and tonics, as "there are no drugs which have any influence upon the embryos in their migration through

the muscles." (Osler.)

DISEASES OF THE RESPIRATORY SYSTEM.

PHYSICAL DIAGNOSIS.

Physical Diagnosis is the art of discriminating disease by means of the eye, the ear and the touch.

The signs thus ascertained are connected with changes or alterations in the form, density, or condition of the structures within, and are known as physical signs.

"Physical signs are, then, the exponents of physical conditions, and

of nothing more." (Da Costa.)

The methods employed in the physical exploration of the chest, are: I, Inspection; II, Palpation; III, Mensuration; IV, Percussion; V, Auscultation; VI, Succussion.

Percussion and auscultation, dealing with sounds, are of the greatest value clinically.

For the purposes of physical exploration, the chest is mapped off into regions or divisions, as follows:—

ANTERIORLY.

First:—Supra-clavicular, Lying above the upper edge of the clavicle, usually about an inch in extent.

Second:—Clavicular, Corresponding to the inner two-thirds of the clavicle.

Third:—Infra-clavicular, From the clavicle to the lower border of the third rib.

Fourth: - Mammary, Between the third and sixth ribs.

Fifth: - Infra-mammary, Downward from the sixth rib.

LATERALLY.

First:—Axillary, That portion above the sixth rib.

Second:—Infra-axillary, That portion below the sixth rib.

POSTERIORLY.

First: -- Supra-scapular, That portion above the scapula.

Second:—Scapular, That portion covered by the scapula.

Third:—Inter-scapular, That portion between the scapulæ.

Fourth: - Infra-scapular, That portion below the angle of the scapula.

INSPECTION.

Inspection signifies "the act of looking." Views of the chest should be taken from the sides and behind as well as from the front; for which purpose a good light should be obtained, and the patient be placed in as easy and comfortable a position as is possible.

Inspection reveals the *form*, *size*, *color* and *movements* of the chest, as well as the condition of the superficial parts.

In *health* the sides of the chest are for the most part *symmetrical* in form, size, color and movements, both sides rising equally during the act of inspiration, and falling equally during the act of expiration. During the act of inspiration the intercostal spaces in the lower two-thirds of the chest become more hollow, as also do the supra-clavicular fossæ.

Inspiration is almost entirely the result of muscular action; expiration, on the other hand, is chiefly due to the elasticity of the lungs and chest walls, aided somewhat in forced respiration by muscular action. The movement of inspiration by inspection is of longer duration than that of expiration, and the pause between the acts but momentary.

The respiratory movement is visible over the whole thorax, although in males and in children it is most distinct at the lower portion (inferior costal breathing), while in the female it is most distinct at the upper portion of the chest (superior costal breathing).

PALPATION.

By palpation is meant the application of the palmar surfaces of the hands and fingers to the chest, by which means we appreciate impressions which are capable of being conveyed by the sense of touch.

The objects of palpation are:-

First:—To give more accurate information regarding what is revealed by inspection.

Second:—To locate spots of soreness, the density and condition of tumors, if any be present, the state of the chest walls, the frequency of the breathing, and the action of the heart.

Third:—To determine the existence and character of the various kinds of *fremitus* (vibrations).

By fremitus is understood certain tactile impressions or vibrations conveyed to the surface of the chest, which are classed and produced as follows:—

First:—Vocal fremitus, produced by the act of speaking or crying.

Second:—Tussive fremitus, produced by the act of coughing; of value especially when the voice is very weak.

Third:—Bronchial fremitus, produced by the passage of air through mucus, blood, or pus, in the bronchial tubes, during the act of respiration.

Fourth:—Friction fremitus, produced by the rubbing together of the roughened surfaces of the pleura.

When the normal chest vibrates lightly, it is termed the normal vocal fremitus.

The vocal fremitus is more distinct upon the right side toward the apex.

If the lung be consolidated (denser), the vibration is greater and more easily distinguished,—the vocal fremitus is increased.

In feeble persons, or when any cause interferes with the transmission of the vibrations, the vocal fremitus is diminished or absent.

MENSURATION.

Mensuration, or measurement of the chest, is of little practical importance, and hence seldom performed. The only measurement likely to be required is the *circular* or *circumferential*, in different

parts of the chest, which is performed with either an ordinary graduated tape measure or a double tape measure, made by uniting two tapes in such a manner that they start in opposite directions from the same point at the *mid-spinal line*. The tapes drawn around each side until they meet at the *mid-sternal line*, on a line immediately above the nipple, or on the level of the sixth rib near its attachment to the cartilage—the sixth costo-sternal joint—the patient first being directed to effect a complete expiration, the number of inches noted, and then to take a deep inspiration, the increase in inches noted, the difference between the two giving a rough estimate of the capacity of the lungs.

In right-handed persons the right side is usually one-half to three-fourths of an inch larger than the left; if larger than this it is usually the result of some abnormal condition.

In well-developed men the chest measures at the upper part about thirty-three to thirty-five inches during expiration, and is increased fully three inches upon inspiration.

PERCUSSION.

Percussion, or "The act of striking," to ascertain the composition of structures, affords signs and information of great value in diagnosis.

There are two methods employed, immediate and mediate.

Immediate, or direct percussion, is performed by striking the thorax directly with the points of the fingers or the palmar surface of the hand. This method of percussion has been generally abandoned, as it does not enable the physician to distinguish, with sufficient correctness, between the various shades of difference in the pitch or quality of percussion sounds.

Mediate, or indirect percussion, may be practiced in three different ways, to wit:—

First.—With the finger of one hand interposed between the body percussed and the percussing finger.

Second:—With the finger acting as a pleximeter and the percussion hammer.

Third: -With the percussion hammer and the pleximeter.

The first of these modes affords the most correct and ready information regarding the *resistance* of the parts percussed. The skillful

use of the fingers is more difficult to acquire than that of the pleximeter and hammer; but if the examiner has acquired sufficient skill in its performance, an absolutely accurate result may be obtained. "He who is skilled in digital percussion will be able to percuss equally well with the hammer, the inverse of which does not always hold good." In addition to being proficient in the technical modus operandi, it is necessary to possess a sensitive ear, educated to distinguish between the various shades of the sounds.

When the fingers are employed, it is a matter of choice whether one or more fingers are used as the pleximeter. Usually the last phalanx of the first or second fingers of the left hand are used, the other fingers being raised from the chest, so as not to interfere with the sound vibrations; they should be applied firmly and evenly to the surface, thus preventing the slipping of the soft parts, and also to determine the resistance of the chest walls when the blow is given. The rounded ends of the first and second fingers of the right hand are used as a hammer, striking the pleximeter fingers in such a manner that the nails shall not touch the skin of the underlying fingers. The force employed varies in different regions, but usually, for the chest, should be only of moderate degree. Forcible percussion is of use only when he sound of deep-seated organs is desired.

The *stroke* should be made perpendicularly to the surface and not slanting, as is too often done. The whole movement should proceed only from the *wrist-joint*, and ought not to be too rapid or unequal, or of great force, the fingers being rapidly withdrawn, so as not to interfere with the vibrations.

The objects of percussion are to elicit certain *sounds*, and the amount of *resistance* or *elasticity* of the organs percussed.

The main sounds elicited by percussion are the *dull, clear* and *tympanitic*. Familiarity with the *intensity*, *character* and *pitch* of each of these sounds is essential.

When percussing the healthy chest, the sound obtained is termed the normal pulmonary resonance. It is of variable intensity, depending upon the force of the stroke employed and the amount of adipose and muscular tissues covering the thorax, and the tension of the chest walls.

There is no exact standard of the normal pulmonary or vesicular resonance, but if the two sides of the chest are compared, the normal standard of each person is obtained.

The character is termed pulmonary or clear, as characteristic of the healthy chest wall. The pitch is always relatively low.

The sounds elicited by percussing a healthy chest are not, however, alike over all its parts.

Anteriorly, the portion of lung above the clavicle yields a sound which becomes somewhat tympanitic, as the trachea is approached.

Over the *clavicle* the sound is *clear* and pulmonary at the centre of the bone, but at the scapular extremity it is duller, and towards the sternum it becomes somewhat tympanitic.

At the *infra-clavicular region* the resonance is *clear* and distinct, but little resistance being offered to the percussing finger, and the sound elicited may be taken as the type of the pulmonary resonance. In this region, however, a slight disparity exists between the two sides; on the right side the sound is less clear, shorter and of a higher pitch than on the left side.

In the *mammary region* of the right side the resonance of the lung is not so clear, the sound being modified by the size of the mamma and the upper border of the liver. On the left side the heart deadens the sound from the fourth to the sixth rib, and in a transverse direction, from the sternum to the left nipple. This dull sound in the left mammary region is lessened in extent during full inspiration, and in emphysema, when the lung more completely covers the heart.

In the *infra-mammary region* on the right side the percussion note is *dull*, except during the act of complete inspiration, when the liver is displaced downward by the inflated lung. In the left *infra-mammary region* the sound consists of a mixture of the dull sound of the heart and spleen and of the clear sound of the lung, together with the tympanitic sound of the stomach.

Over the upper part of the *sternum*—above the third rib—the sound is slightly *tympanitic*. Below the third rib, over the sternum, the sound is dull, due to the presence of the heart and liver.

The position exercises some influence on the results of percussion. More accurate results are obtained when the patient is standing or sitting than when recumbent. While the front of the chest is percussed, the arms should hang loosely by the sides; the hands may be clasped across the top of the head during the percussion of the axilkary region; during the examination of the back the head must be bent forward and the arms tightly crossed in front.

On the *posterior* surface of the chest the sound also varies according to the part percussed.

Over the scapulæ the sound is duller than between these bones or below their inferior angles.

Over the *infra-scapular region* a *clear* sound is obtained as far as the lower border of the tenth rib on the right side, where the dullness of the liver begins. On the left side, below the angle of the scapula, the percussion sound is tympanitic if the intestines are distended, or it may be slightly dull if the spleen be enlarged.

In the axillary region the sound is clear and distinct on each side.

In the *infra-axillary* region of the right side the sound is *duller*, owing to the presence of the liver; at the corresponding situation on the left side, the sound is *clear* or *tympanitic*, from the distention of the stomach, and at the ninth or tenth rib of the left axillary region dullness and the sense of resistance mark the location of the spleen.

The sound obtained by percussion of the *unhealthy* or abnormal chest are as follows:—

First:—Hyper-resonance or an increase of the normal pulmonary resonance is due to the relative increase in the proportion of air to the solid tissues of the lung, providing the tension of the chest walls be not altered, occurring in emphysema of the lungs, atrophy of the lungs, or consolidation of the opposite lung.

Second:—Dullness or an absence of resonance, due to the relative increase of solid tissues in proportion to the amount of air, as seen in the different stages of phthisis, in pneumonia, pleural effusion and hydrothorax.

The pitch is increased or heightened in proportion to the diminution of the amount of the air and the increase of the solids.

If there be entire want of resonance, the percussion note is said to be *flat*; if there is a slight decrease in the resonance of the part the note is said to be *impaired*.

The sense of *resistance* is greater, the more marked the consolidation of the lungs and the greater the tension of the chest walls.

Third:—Tympanitic, or the drum-like percussion note, is a non-vesicular sound having the character elicited by percussing over the normal intestines; wherever heard it indicates the presence of air in conditions similar to that of the intestines, to wit: inclosed in walls which are yielding, but neither tense nor very thick.

When elicited over the chest it may be due to the transmitted sound of the distended stomach or colon. It is obtained over the chest in pneumothorax, in moderate pleural effusions above the level of the liquid, over the seat of cavities in the pulmonary tissues, and in ædema of the lungs.

The *tympanitic* percussion note differs from the normal pulmonary resonance in being more ringing in character and of a *higher pitch*.

The amplioric or metallic sound is in reality a concentrated tympanitic sound of high pitch, and denotes a large cavity with firm, elastic walls.

The cracked-pot or cracked-metal sound is another variety of the tympanitic sound. The condition most commonly producing this sound is a cavity in the lung tissue, communicating with a bronchial tube. It requires for its development a strong, quick blow of the percussing finger, with the patient's mouth open.

RESPIRATORY PERCUSSION.

The percussion sound will vary greatly with the respiratory movements. If a full inspiration be taken and percussion performed, then a full expiration taken and percussion performed, and then the chest percussed during the normal respiration, slight changes in the character and pitch of the note are obtained, which otherwise would escape detection. Prof. DaCosta has designated this method, respiratory percussion.

AUSCULTATORY PERCUSSION.

This method consists in listening with a stethoscope applied to the thorax, to the sounds elicited by percussion. "It is a serviceable means of determining with accuracy the boundaries of various organs, as those of the lungs or heart, or of the liver or spleen, and yields particularly exact results when carried out with the double stethoscope."

AUSCULTATION.

Auscultation, or listening to the sounds produced within the chest during the act of respiration, coughing, or speaking, furnishes the most reliable means of studying the condition of the lungs, and is, therefore, the most valuable method of discriminating between the various conditions which may affect the lungs.

Auscultation is either immediate or mediate.

It is *immediate* when the ear is applied directly to the chest, which may be either denuded or thinly covered.

It is *mediate* when the sounds are conducted to the ear by means of a tubular instrument, termed a *stethoscope*.

For ordinary purposes, *immediate*, or direct auscultation is sufficient, but when it is desirable to analyze circumscribed sounds, as in diseases of the heart, or where the patient objects to this method, on the score of delicacy, or the auscultator objects, on account of the uncleanliness of the person examined, the stethoscope is to be preferred. Moreover there are certain parts of the chest which can only be explored satisfactorily by the aid of a stethoscope, and again this instrument has the additional advantage of *intensifying* the sound

In auscultation, the following rules, formulated by Prof. DaCosta, should be observed:—

- "I. Place yourself and your patient in a position which is the least constrained and permits of the most accurate application of the ear or stethoscope to the surface. Above all, avoid stooping, or having the head too low."
- "2. Let the chest be bare, or what is better, covered only with a towel or a thin shirt."
- "3. If a stethoscope be employed, apply closely to the surface, but abstain from pressing with it. This may be obviated by steadying the instrument, immediately above its expanded extremity, between the thumb and the index finger."
- "4. Examine repeatedly the different portions of the chest, and compare them with one another while the patient is breathing quietly. Making him cough, or draw a full breath, is, at times, of service; especially the former, when he does not know how to breathe."

SOUNDS IN HEALTH.

If the ear be applied over the *larynx or trachea* of a healthy person, a sound is heard with both the act of inspiration and expiration. Its *intensity* is *variable*, its *pitch high*, and its *quality tubular* (to wit: a current of air passing through a tube—the larynx or trachea). The duration of the sound during inspiration being somewhat longer than during expiration. A *short pause* follows the act of expiration.

This sound is termed the normal laryngeal respiration, and is

identical in character, duration and pitch with an important morbid sound, termed bronchial respiration.

The sound heard by placing the ear over the lung tissue is different; it is produced in the very finest bronchial tubes and air cells by their expansion and contraction, and is termed the *normal vesicular murmur*.

The inspiratory portion of the sound is of variable intensity, its pitch is low, its quality soft and breezy, designated vesicular; its duration is during the entire act of inspiration.

The expiratory portion of the sound is not always perceptible; it is of feeble intensity, very low pitch, its character soft and blowing, and its duration much less than the act of inspiration.

It is to be remembered, however, that the vesicular murmur will be found to vary in the different regions on the same side, and in corresponding regions on the two sides of the chest. These variations within the range of health are especially important, and should be memorized.

Infra-clavicular Region.—The vesicular murmur in this region on either side is much more distinct than over any other part of the chest.

On the left side the *inspiratory sound* is of greater intensity, of *lower pitch*, and more distinctly vesicular in quality than that heard upon the right side. On the right side the *expiratory sound* is nearly or quite the same in length as the inspiratory sound, and is *higher in pitch* and more *tubular* in quality than the expiratory sound upon the left side.

Supra-scapular Region.—Owing to the small number of air vesicles and the large number of bronchial tubes, and their nearness to the surface, the respiratory murmur has an intense, high-pitched, tubular and expiratory quality.

Scapular Region.—Compared with the infra-clavicular region, the respiratory murmur heard over the scapulæ on either side is more feeble, and the vesicular quality less marked.

Inter-scapular Region.—The murmur in this region differs from the normal laryngeal breathing only in intensity and duration.

Infra-scapular Region.—The murmur in this region very closely resembles that heard in the left infra-clavicular region.

Mammary and Infra-mammary Regions.—The murmur in these regions differs from that heard in the infra-clavicular region, in being of less intensity.

Axillary and Infra-axillary Regions.—The respiratory sound in the axillary regions is as intense as in any portion of the chest. In the infra-axillary regions the intensity is less and the pitch lower.

VOICE IN HEALTH.

If the ear be applied over the larynx or trachea of a healthy person, and he be directed to count "twenty-one, twenty-two, twenty-three," in a uniform tone and with moderate force, there is perceived a strong resonance, with a sensation of concussion or shock, and a sense of vibration, thrill or fremitus, the voice seeming to be concentrated and near the ear. Often the articulated words are distinctly transmitted (laryngophony).

The sounds thus heard are termed the normal laryngeal resonance.

If the ear or stethoscope be applied over the third rib anteriorly, on either side of the chest of a healthy person, and he be directed to count "twenty-one, twenty-two, twenty-three," in a uniform tone, with moderate force, a confused, distant hum is perceived, of variable intensity, accompanied with more or less vibration, thrill or fremitus, most distinct in adults, but notably weaker in women than in men.

This sound is termed the normal vocal resonance.

If the ear or stethoscope be applied over the third rib anteriorly, of a healthy person, and he be directed to whisper, in a uniform manner, the words, "twenty-one, twenty-two, twenty-three," there is heard a sound corresponding closely in character to the sound of expiration over the same region during the act of forced respiration; or, in other words, a feeble, low-pitched, blowing sound.

This sound is termed the *normal bronchial whisper*, and is produced by the air in the bronchial tubes during the act of expiration.

SOUNDS IN DISEASE.

The vesicular murmur may undergo, in disease, changes in its intensity, its rhythm, and in its character.

The intensity of the respiratory murmur may be:-

- I. Exaggerated or increased.
- 2. Diminished or feeble.
- 3. Absent or suppressed.

Exaggerated respiration differs from the normal vesicular respiration only in an increase in the intensity of the respiratory sounds. When general over one lung, it will usually indicate de-

ficient action of other parts. In this manner an effusion compressing the lung, one-sided deposits, obstruction of the bronchial tubes by secretion, or inflammation of the lung structure, necessitate a *supplementary* respiration in a healthy portion of the same lung or the lung upon the opposite side. From its resemblance to the loud, strong, quick respiration of young children, it has been termed *puerile* respiration.

Exaggerated respiration is, therefore, to be regarded as indirect evidence of disease in some portion of the pulmonary tissue.

Diminished respiration, called also senile respiration, as being characteristic of old age, is characterized by diminished intensity and duration of the sound. In the large majority of instances the inspiration suffers the greatest, the expiratory sound not diminishing in the same proportion. In asthma, emphysema, diseases of the larynx and bronchial tubes, pleuritic pain, rheumatism or paralysis of the chest walls, or in thickening of the pleural membrane, we observe superficial or diminished respiration. When one side of the chest is partially filled with fluid, we may hear a deep-seated, but feeble breath sound.

Absent or suppressed respiration occurs whenever the action of the lung is suspended; this may be from external pressure, as when the lung is compressed by the presence of fluid or air in the pleural cavity, or when complete obstruction of the bronchial tubes prevents the air from either entering or escaping from the lungs.

The rhythm of the respiratory murmur may be

- I. Interrupted or jerky.
- 2. The interval between inspiration and expiration prolonged.
- 3. Expiration prolonged.

In health the inspiratory and expiratory sounds are even and continuous, with a short interval between each act; this may be altered in disease, and both sounds, especially the inspiratory, have an interrupted or jerky character, termed "cog-wheel respiration."

This jerky breathing is noted in some spasmodic affections of the air tubes, in hysteria, the earliest stages of pleurisy, pleurodynia, and the early stages of pulmonary phthisis. It is most frequently associated with phthisis, due probably to the adhering to the walls of the finer bronchial tubes of tough mucus, which obstructs the free entrance and exit of the air; it is usually most notable under the clavicles.

The interval between inspiration and expiration may be prolonged, instead of these two sounds closely succeeding one another. When this occurs the inspiratory sound may be shortened, or the expiratory sound may be delayed in its commencement. If the inspiratory sound is shortened, it is the result of consolidation of the lungs; if the expiratory sound is delayed, it is the result of lessened elasticity of the lung structure, and is most commonly associated with emphysema.

Prolonged expiration denotes that the air is obstructed in its exit from the lungs. It may be the result of diminished elasticity, the result of emphysema, or from the deposit of tubercles, which impair the contractile power of the lungs. If the former, it is associated with clearness on percussion; if the latter, however, with impaired resonance on percussion. When prolonged expiration is detected at the apex of the lung, and is associated with impairment of the normal pulmonary resonance, it is for the most part the result of a tubercular deposit.

The quality of the respiratory murmur may be

- 1. Harsh, termed vesiculo-bronchial respiration.
- 2. Bronchial.
- 3. Cavernous.
- 4. Amphoric.

Harsh respiration, or, as it is termed by Prof. DaCosta, vesiculobronchial respiration, is that variety in which both the inspiratory and expiratory sounds have lost their natural softness. It generally indicates more or less consolidation of lung tissue. In normal vesicular respiration the sounds produced by the air expanding the air cells and finer bronchial tubes obscures the sound produced by the passage of air through the larger bronchial tubes, the healthy lung being an imperfect conductor of sound, so that as soon as any portion of the lung becomes consolidated the vesicular element of the respiratory sound is diminished, the bronchial element becoming prominent. Harsh respiration is, then, a union of the vesicular and bronchial sounds, being a vesicular sound mixed with some of the qualities of a bronchial sound, the expiration being prolonged and tubular in character. It is present when the bronchial mucous membrane is swollen, as in the earlier stages of bronchitis, also in the earlier stages of phthisis and pneumonia.

Bronchial respiration is characterized by an entire absence of

all the vesicular quality. *Inspiration* is of *high pitch* and *tubular* in character; *expiration* still *higher in pitch*, of greater intensity, *prolonged* and *tubular* in quality; the two sounds being separated by a brief interval.

The bronchial respiration encountered in disease closely resembles that heard in health over the larynx or trachea. Whenever bronchial respiration is present where, in health, the normal vesicular murmur should be heard, it indicates consolidation of the lung structure.

Cavernous respiration is a variety of the bronchial respiration, at least so far as the quality of the sound is concerned. It is essentially a blowing sound, yet not always heard during both the act of inspiration and expiration, being often only perceptible in the one, and in the other mixed with gurgling sounds. Its pitch is lower than that of ordinary bronchial respiration, and its character is hollow.

For its production there must be a cavity of considerable size in the lung substance, not filled with fluid, near the surface of the chest walls, communicating with a bronchial tube. It is met with most commonly in the last stages of pulmonary consumption, although hollow spaces of any kind, from abscess or dilatation of the bronchial tubes, occasion it.

Amphoric respiration is a blowing respiration, having a musical or metallic quality. It is a variety of bronchial respiration produced in a large cavity with firm walls, permitting the reflection of the sound. An imitation of this sound, though only an imperfect one, is produced by blowing over the mouth of an empty bottle. The amphoric character is present with both the act of inspiration and expiration.

Amphoric or metallic respiration is indicative of a large cavity, not common in phthisis, but much oftener heard at the upper part of a lung compressed by fluid and air, as in pneumo-hydrothorax.

RÂLES.

Râles, or, as they are termed, adventitious sounds, because they have no analogue in the healthy state, cannot be considered as modifications of the normal respiration.

Grouped according to the anatomical situation in which they are produced, we have:—

1. Laryngeal and tracheal râles.

- 2. Bronchial râles.
- 3. Vesicular râles.
- 4. Cavernous râles.
- 5. Pleural râles.

Rales may be divided into two groups, according to their character, to wit: *dry* and *moist*, and may be audible either during the act of inspiration or expiration, or during both.

Dry râles, for the most part are produced by the *vibration* of thick fluids which the air cannot break up, and which, therefore, temporarily lessens the calibre of the bronchial tubes. When this narrowing exists in the smaller bronchial tubes the resulting sound is *high-pitched* or the râle is said to be *sibilant* or whistling; when the narrowing exists in the larger bronchial tubes, the râle is *low-pitched*, more musical in character, or *sonorous*.

Dry râles are particularly prone to be dislodged by coughing, and when they are uninfluenced by the acts of breathing or coughing, they do not depend upon the presence of secretions, but upon the narrowing of the air tubes from the pressure of tumors, or from a thickened fold of mucous membrane, or from a spasmodic contraction of the air tubes.

Moist râles are those produced by the air passing through thin fluids, such as mucus, blood, serum, or pus, during the respiratory movements. When the fluid exists in the smaller bronchial tubes, the râles are termed *small bubbling*, mucous, or *subcrepitant*. When the fluid exists in the large bronchial tubes, the râles are said to be *large bubbling* or mucous.

Moist râles are not persistent, but vary in intensity, and shift their positions as the air drives the liquid which occasions them before it, or during violent attacks of coughing, or after copious expectoration.

Laryngeal and tracheal râles are those produced within the larynx and trachea, and may be either moist or dry. The moist or bubbling sounds, produced when mucus or other liquids accumulate in this part of the air tubes, frequently occur in the moribund state, and are then known as the "death rattles." When not due to this condition they denote either insensibility to the presence of liquid, as in stupor or coma, or inability to remove liquid by the acts of expectoration, as in croup or inflammation of these parts in the very feeble.

The dry râles produced within the larynx or trachea are generally

caused by spasm of the glottis, to wit: laryngismus stridulus, whooping cough or croup, or from the presence of a foreign body in the part.

Bronchial râles, resulting from the passage of air through the thin liquid, occasion bubbling sounds. When the liquid is present in the large-sized bronchial tubes, the râles are said to be large bubbling, or large mucous râles, occurring in acute or chronic bronchitis.

When the liquid is in the smaller bronchial tubes, the resulting râle is called *small bubbling*, small mucous, or *subcrepitant*, also occurring in acute or chronic bronchitis.

Bronchial râles due to the narrowing of the tube by its spasmodic contraction, or to the presence of tough, tenacious mucus, which is set in vibration by the passage of the air through the bronchial tubes, are termed dry bronchial râles. Frequently they are suggestive of certain familiar sounds, such as snoring, cooing, humming, or wheezing, or they are often musical notes. When produced in the smaller bronchial tubes, they are termed *sibilant*, or high-pitched râles: when produced in the larger bronchial tubes, they are termed *sonorous* or low-pitched râles. They principally occur in the dry stage of bronchitis, or during an asthmatic paroxysm.

The vesicular râle, or as it is more commonly termed, the *crepitant râle*, is produced within the air vesicles or at the terminal portion of the smaller bronchial tubes.

It is to be distinguished from very fine bubbling sounds, or the subcrepitant râle. "It is a very fine sound, or rather series of very fine uniform sounds, occurring in puffs and limited to inspiration." (Da Costa.) It resembles the noise occasioned by throwing salt on the fire, or alternately pressing and separating the thumb and finger, moistened with a solution of gum arabic, and held near the ear, or rubbing together a lock of dry hair near the ear.

The *crepitant râle* is produced by the movement of fluid in the air cells or in the finest extremities of the bronchial tubes, or by the forcing open, during the act of inspiration, of the air cells agglutinated by exuded lymph. These sounds may be defined as being very fine, dry, crackling sounds, heard at the end of inspiration. They are usually present in the first stage of pneumonia, but when limited to the apices, are significant of the incipient stage of phthisis.

Cavernous râles, or, as they are commonly termed, gurgling

râles, are produced in a pulmonary cavity of considerable size, containing a large amount of liquid communicating freely with a bronchial tube. The sound is occasioned by the agitation of the liquid within the cavity, and may be compared to the sound produced by the boiling of liquid in a flask or large test-tube. The sound is sometimes high-pitched or musical, whence it has been termed "amphoric gurgling," but it is generally low in pitch. The râle is heard almost exclusively during the act of inspiration, and its diagnostic importance relates to the advanced stage of phthisis.

Pleural râles may be either dry or moist.

Dry pleural râles, or as they are more commonly termed, friction sounds, are occasioned when the surfaces of the pleuræ are covered with a glutinous substance preventing the unobstructed movements of the pleural surfaces upon each other during the respiratory acts, for in health, these movements occasion no sound whatever. The sounds are generally interrupted or irregular, occurring during the act of inspiration or expiration, or during both acts. The character of the sound is variable, being termed rubbing, grazing, rasping, grating or creaking, according to the intensity of the respiratory acts and the amount of exudation.

They are distinguished by the apparent nearness of the sound of the ear, and are usually intensified by firm pressure of the stethoscope upon the chest. When the chest is fixed, especially at the lower two-thirds, and the ear applied over the seat of the sound, it will be found to have disappeared. The sound is diagnostic of the first stage of pleurisy.

Moist friction sounds are produced in the same manner as those just mentioned, the exudation being softened in character. This sound is frequently confounded with moist bronchial râles, and its discrimination is often only positive by a careful study of the symptoms and concomitant signs present.

Metallic tinkling is a sign of pneumo-hydrothorax with perforation of the lung, and when found is usually diagnostic of this affection, although it occurs rarely in cases of phthisis with a large cavity, the physical conditions for its production being similar to those in pneumo-hydrothorax, to wit: a space of considerable size containing air and liquid, the space communicating with the bronchial tubes.

It consists of a series of *tinkling sounds*, of high pitch, silvery or metallic in tone, and is very well imitated by dropping a small marble

into a metallic vase. It occurs irregularly, not being present with every act of breathing, and may be produced by forced, when not heard during tranquil breathing.

Were it not for the location and the absence of concomitant signs it might be confounded with tinkling sounds sometimes produced within the stomach and transverse colon.

THE VOICE IN DISEASE.

The normal vocal resonance, as heard over the third rib of the chest anteriorly on either side, may have its *intensity*—

- I. Diminished or absent.
- 2. Increased or exaggerated.

Or its resonance may be of the character of-

- 3. Bronchophony.
- 4. Pectoriloquy.
- 5. Ægophony.
- 6. Amphoric voice.

The vocal resonance may be diminished or feeble in bronchitis with free secretion, pleurisy with effusion, or in complete consolidation of the lung structure and the bronchial tubes.

The vocal resonance is absent in pneumothorax and in pleurisy with effusion.

Exaggerated vocal resonance differs from the normal vocal resonance in a slight increase of its density. It denotes a slight degree of solidification of lung tissue, and is chiefly of value in the diagnosis of tubercle.

Bronchophony, or the voice concentrated near the ear, raised in pitch and in intensity, denotes complete consolidation of the pulmonary tissue in those parts in which the sound is abnormally present.

Pectoriloquy is complete transmission of the voice to the ear, the articulated words being distinctly recognized. It has a close resemblance to the resonance heard over the larynx in health. Its presence indicates either a pulmonary cavity or more complete consolidation—in other words, an exaggerated bronchophony.

Ægophony is a modification of bronchophony, consisting in tremulousness of the voice, its character nasal or bleating, somewhat suggestive of the cry of a goat. When heard, it may be considered a sign of pleurisy with slight effusion, or of pleuro-pneumonia.

Amphoric voice, or "the echo," as it is sometimes called, is a musical sound, of a somewhat hollow, metallic character, like that produced by blowing into an empty bottle. It is sometimes produced in large cavities within the lung, but is especially incident to pneumothorax.

Increased bronchial whisper is a sound in which the whispered words are abnormally intense, and higher in pitch than the normal bronchial whisper. It has the same significance as exaggerated vocal resonance.

SUCCUSSION.

The succussion or splashing sound is pathognomonic of one affection, namely, pneumo-hydrothorax.

It is obtained by jerking the body of a patient with a quick, somewhat forcible movement, the ear being very near or in contact with the chest.

The sound is like that produced when a small keg, partially filled with liquid, is shaken. The only liability to error is in confounding this splashing sound with that sometimes produced within the stomach; but attention to concomitant signs and the symptoms will always protect against this error.

ASSOCIATION OF THE PHYSICAL SIGNS (DA COSTA).

"As many of the signs elicited by the various methods of physical diagnosis depend on the same physical conditions, they may be studied in groups. The following will be usually found to be associated:—

Percussion.	OF RESPIRATION.	AUSCULTATION OF VOICE.		PHYSICAL CONDITIONS.			
Clear	Vesicular murmur or its modifi- cation.	Normal vocal resonance.	Unimpaired.	Lung tissue healthy or nearly so; at any rate, no increased density from deposits, etc.			
Dull	Bronchial, or harsh respiration,	Bronchophony.	Increased.	Solidification of pulmonary structure.			
	Absent respi- ration.	Absent voice.	Diminished or absent.	Effusion into pleural sac.			
Tympanitic.	Cavernous or feeble, ac- cording to cause.	Uncertain; cavernous or diminished.	Uncertain; mostly di- minished.	Increased quantity of air within the chest, due to a cavity or to overdistention of the air cells.			
Amphoric or metallic.	Amphoric or metallic.	Amphoric or metallic.	Mostly di- minished.	Large cavity with elastic walls.			
Cracked metal sound.	Cavernous respiration.	Cavernous respiration.	Uncertain,	Generally a cavity com- municating with a bron- chial tube.			

DISEASES OF THE NASAL PASSAGES.

ACUTE NASAL CATARRH.

Synonyms. Acute rhinitis; acute coryza; "cold in the head." Definition. An acute catarrhal inflammation of the mucous membrane (pituitary or Schneiderian membrane) lining the nose and the cavities communicating with it; characterized by feverishness, feeling of fullness and discomfort in the head, and attended with discharges of fluid, watery, mucous, or muco-purulent in character.

Pathological Anatomy. Hyperamia of the mucous membrane, attended with redness, swelling, and deficient secretion. This tumefaction is partly increased by an adematous infiltration, causing a quantity of colorless, salty, and very thin liquid to flow from the nose. The secretion soon assumes the character of thick, tenacious mucus or muco-pus, due to the desquamation of the epithelium of the nasal mucous membrane, and a copious generation of young cells, the hyperæmia and the swelling of the membrane diminishing.

The respiratory portions of the nasal fossæ are more markedly affected than are the olfactory.

Rarely, and then in new-born infants and those affected with the eruptive fevers, the exudation in the nasal passages is of a fibrinous nature, somewhat similar to that observed in diphtheria.

Causes. Atmospherical changes are the most frequent and influential. Exposure of the neck to a draught of cold air, or of the feet and ankles to cold and dampness, or changing from a warm to a cold atmosphere suddenly, are among the most usual causes. Irritating gases and vapors, dust, certain powders, as ipecac and tobacco. The scrofulous taint and the rheumatic diathesis seem to render the mucous membrane susceptible to frequent attacks.

Acute coryza is usually present in the initial stage of measles and influenza.

Epidemic influence occasionally prevails on an extensive scale. The poison of syphilis or the use of the iodide of potassium not unfrequently act as exciting causes.

At times the catarrh seems to spread by contagion.

Symptoms. "A cold in the head" is usually preceded by a feeling of lassitude or weariness and more or less frontal headache; then occur irregular chilly sensations in the back, followed by more or less feverishness and an uncomfortable feeling of dryness in the nares, with a strong inclination to sneeze. This is soon followed by an abundant watery and saline discharge, which is continually dripping from the nostrils, or occasions an attack of sneezing followed by blowing the nose, which relieves the congested and swollen membrane for a few moments. The relief is temporary, however, the fullness of the head and difficult obstructed nasal respiration rapidly returning. The anterior nares are red and inflamed, and the eyes red and suffused with tears, through partial or entire closure of the tear ducts. The discharge soon assumes a purulent character. The voice has a peculiar tone, rather nasal and muffled in character. Within a few days the swelling subsides, and secretion lessens, health being restored in about ten days from the beginning of the attack.

When the attack has almost terminated hard crusts may form within the nostrils, either on the septum or turbinated bones, which are with difficulty expelled by blowing the nose.

Complications. *Irritation* and *swelling* of the upper lip, from repeated blowing of the nose and the constant contact of the irritating discharge.

Extension of the catarrh to the *cthmoid* or *sphenoid cavities* or *frontal sinus*, causing increased and severe frontal headache; or to the *antrum* of *Highmore*, causing tenderness over one or both cheeks.

Extension to the *Eustachian tube* and *middle ear*, causing impaired hearing; or to the *pharynx* or *larynx*, causing cough.

Duration. In mild cases about one week; severe cases continue, more or less marked, for two weeks.

Prognosis. Favorable if early and proper treatment be instituted; if neglected, the catarrh tends to become chronic. In very young infants, if the catarrh is not rapidly relieved, loss of flesh and strength occur, from inability to take the breast.

Treatment. Attacks the result of atmospherical causes may be aborted by the early administration of quininæ sulphas, gr. x-xv, with morphinæ sulphas, gr. ¼, or the early use of pulvis ipecacuanhæ et opii, gr. v, repeated in two hours.

The following *errhine* used at the very onset has proved successful in *aborting* many cases:—

R. Aluminis. Bismuthi bicarb.. Pulv. talc. Morphinæ hydrochlor...... gr. ij. M. et ft. chart. No. xx.

SIG.—Insufflate one powder in each nostril after clearing the nose. (Sajous.)

If the attack has already developed, relief is soon afforded by tinctura belladonnæ, gtt. ij, every hour until six doses are taken, after which one drop every two or three hours until the physiological actions of the drug are produced; if much fever be present, tinctura aconiti, gtt. i-ij, may be added; the addition of camphora is of value, in fact, camphora in full doses at the onset and locally will often abort an acute catarrh. The following combination of Dr. Sajous is often successful :---

Aq. camphoræ, ad M.

SIG.—One teaspoonful in water every hour or two.

Attacks of acute rhinitis unaccompanied by febrile reaction are generally promptly aborted by a four per cent, solution of cocaine dropped in the nostrils, repeated every half hour.

With either of the above plans may be added one of the following errhines :-

	К.	Bismu	th, subn	ıt., .							4		3 V)		
		Pulv.	acaciæ,										3 ij		
		Morph	inæ hyd	rochl	or.,								gr. ij.	M.	
	SIG	-Ever	y hour o	r two	١,	(F	erri	er.)						
Or—															
O1	R.	Pulv	cuhehæ										- i		

Bismuth. subnit., 3 ij Morphinæ hydrochlor., gr. ij. M. Sig.—Used by insufflation every two or three hours.

Acute coryza occurring in infants at the breast is controlled by either one of the following errhines thrown into the nose, with a powder blower; finely powdered saccharum album, or equal parts of finely powdered saccharum album and camphoræ, or Robinson's errhine of saccharum album and camphora, each half ounce, finely powdered, and acidum tannicum, gr. xl.

Attacks of nasal catarrh due to the poison of syphilis should at once be placed upon the proper constitutional treatment.

Attacks of nasal catarrh associated with the eruptive or mild fevers require no special treatment.

It is well to remember that attacks of nasal catarrh occurring in very young children are generally the result of hereditary syphilis, and should be treated accordingly.

CHRONIC NASAL CATARRH.

Synonyms. Chronic rhinitis; chronic coryza.

Definition. A chronic inflammation of the mucous membrane lining the nasal passages, with more or less alteration of structure; characterized by a sensation of fullness in the nares, increased secretion, and a perversion of the special sense of smell and of hearing.

Causes. The result of repeated attacks of the acute variety; inhalation of irritating vapors and dust; syphilis and scrofula.

Pathological Anatomy. The mucous membrane of the nares is thickened, of a dark-red, sometimes grayish color, the superficial veins dilated and varicose, often forming polypoid enlargements. In many cases there is ulceration of the structure, with more or less loss of substance; the secretion is thick, tough, of a greenish character, and often very fetid; large collections of dried mucus are often formed upon the turbinated bones and septum.

Symptoms. A feeling of *fullness* in the *nares*, *increase* of the *secretion*, the character being thick and greenish, which, dropping posteriorly into the pharynx, causes paroxysms of "hawking," which are more marked in the morning immediately after arising.

The special sense of smell is more or less impaired, and in many cases entirely abolished; the special sense of hearing is more or less diminished, from an extension of the inflammation to the Eustachian tubes; the voice has a peculiar nasal intonation.

An almost constant dull *frontal headache*, associated with a feeling of weight, showing the extension of the disease to the infundibulum and frontal sinus.

Sudden changes of temperature cause acute exacerbation of these symptoms, when there is superadded difficult nasal respiration.

If ulceration of the nares occur, the discharge has a fetid odor. This condition is termed ozena.

From extension of the inflammation to the nasal duct or its obstruction, the tears flow over the malar eminence (*epiphora*), leading to more or less congestion of the eyes.

Diagnosis. Hypertrophy of the turbinated bones and nasopharyngeal catarrh are constantly misnamed chronic nasal catarrh. The rhinoscope readily determines the diagnosis.

Prognosis. Permanent cure is seldom obtained; the disease being so decidedly chronic and obstinate, the treatment is of necessity protracted, and the majority of patients tire of it before a complete cure is effected.

Treatment. If it depends upon diathetic conditions, the cause must be ascertained and treatment directed accordingly.

When no diathetic cause can be determined, attention should be paid to the general health, the secretions constantly attended to, and the diet be nutritious and digestible.

Cleanliness of the nasal passages is of the utmost importance, and is best effected by the *post-nasal syringe*, with either simple or medicated tepid waters, or a cleansing solution, such as Dobell's, to wit:—

DISEASES OF THE PHARYNX.

ACUTE CATARRHAL PHARYNGITIS.

Synonyms. Catarrhal tonsillitis; angina catarrhalis; acute

Definition. An acute catarrhal inflammation of the mucous membrane of the tonsils, uvula, soft palate, and pharynx; characterized by rigors, fever, painful deglutition, coughing, or constant desire to clear the throat, with a more or less decided nasal intonation of the voice.

Causes. Exposure to cold and damp; swallowing hot fluids or food; during the prevalence of scarlatina, measles, erysipelas, influenza, diphtheria, or variola.

Pathological Anatomy. The mucous membrane and submucous tissues of the uvula, soft palate, fauces, tonsils, and pharynx are congested, red, and swollen; the secretion is at first lessened or entirely arrested, later it is increased, but of a thick, tenacious, opaque character. The swelling is most evident at the uvula, due to the amount of relaxed sub-mucous tissue, which is especially thick and long, often resting on the root of the tongue ("the palate is down").

Frequently one or both tonsils are swollen to such an extent that the fauces are completely occluded, and the condition is mistaken for the graver phlegmonous tonsillitis.

In severe attacks of catarrhal angina, white or grayish-white membranous masses form in small, irregular, roundish spots on the reddened mucous membrane of the tonsils, soft palate, and pharynx, causing the affection to be frequently mistaken for diphtheria.

Symptoms. The onset is usually sudden, with rigors, fever, thirst, headache, loss of appetite, coated tongue, bad taste, foul

breath, dryness in the throat, painful deglutition, and constant desire to clear the throat, due to the increased length of the uvula; as the inflammation proceeds the secretions are increased, the fluid often filling the mouth and also causing a constant desire to swallow, each act being associated with acute pains. Not infrequently earache adds to the patient's distress, from extension of the "catarrh" to the Eustachian tubes and tympanum.

In severe attacks of catarrhal pharyngitis, cases which, from the intense hyperæmia, have been termed *erysipelatous* or *erythematous pharyngitis*, the muscles of the palate are infiltrated with serum, which greatly interferes with their function. Under normal conditions the contraction of the muscles of the anterior half arches of the palate prevents the return of the food and drink into the mouth; while the contraction of the muscles of the posterior half arches, together with the uvula, closes the passage to the nose; if the function of these muscles be impaired, fluids would be driven through the nose or back into the mouth by the contractions of the pharynx in the act of deglutition.

In all affections of the pharynx a *nasal* tone is pathognomonic, especially if the muscles of the half arches are interfered with.

Varieties. Exanthematous Pharyngitis is the form of the affection complicating the acute infectious diseases, such as scarlatina, measles, influenza, and smallpox.

Erysipelatous Pharyngitis is the form complicating facial erysipelas; rarely, however, the affection begins in the pharynx, spreading to the face and other parts.

Gangrenous Pharyngilis may occur with diphtheria, scarlatina, erysipelas, smallpox, and typhoid fever. The symptoms assume a typhoid (depressed) character, the termination being usually fatal.

Phlegmonous Pharyngitis is the variety in which is present an accumulation of pus in the submucous and deeper tissues of the pharynx, constituting a retro-pharyngeal abscess. This variety of pharyngitis may follow the penetration of a sharp piece of bone or be secondary to caries of the cervical vertebræ.

Fibrinous Pharyngitis, or, as it is sometimes termed, pseudo-membranous, is considered with croup and diphtheria, of which it constitutes a part.

Diagnosis. On account of the great swelling of the tonsils, it may be mistaken for acute tonsillitis; but the mild inflammatory symptoms should prevent the error.

Cases with membranous deposits upon the tonsils, soft palate, and pharynx are no doubt often misnamed *diphtheria*; the marked difference in the constitutional symptoms should prevent the error.

Prognosis. Favorable, the affection terminating in three or four days by the raising of a quantity of thick, opaque mucus.

Treatment. If the attack is the result of exposure to cold or damp, or a symptom of some one of the infectious diseases, the very best results follow the application of sodii bicarbonas by insufflation. Opium in some form, alone or combined with ipecac or camphora, will often abort an attack of catarrh. Salol, gr. x (reducing size of dose for children), repeated four to six times daily, is a most valuable remedy for relieving the pain in all varieties of acute anginas. If the fever be marked, advantage follows the addition of small doses of tinctura aconiti. In children no one drug can compare with small repeated doses of tinctura aconiti.

Locally, cocaine painted over the inflamed parts, of the strength of a four per centum solution, or used in the form of lozenges, is a valuable remedy. Holding small pellets of ice in the mouth is useful, as is the application of either heat or cold to the angles of the jaws. Gargles or sprays of aluminis (gr. viij-aquæ f3j), ammonii chloridum (gr. xx-aquæ f3j), or potassii chloras (gr. xij-aquæ f3j), used at frequent intervals, often allays the congestion and consequent swelling. For the gangrenous variety stimulants and the local use of argentinitras.

If a retro-pharyngeal abscess develop, evacuate the pus early and give *quinina* and *ferrum* for the constitutional symptoms which may develop. In all varieties the use of pellets of ice is comforting.

ACUTE TONSILLITIS.

Synonyms. Amygdalitis; quinsy; phlegmonous pharyngitis. Definition. An acute parenchymatous inflammation of one or both tonsils, with a strong tendency toward suppuration; characterized by moderate fever, pain in the throat, a constant desire to relieve the throat, painful and difficult deglutition, impeded respiration, and more or less muffling of the voice.

Causes. Generally attributed to exposure to cold, but, in the majority of cases, the exposure is so slight that there must be a pre-

disposition to the affection; for persons once affected are particularly prone to repeated attacks upon the slightest exposure.

Pathological Anatomy. One or both tonsils will be seen, on inspection, to project from its bed, as a rounded, deep red body, which may even extend beyond the median line, when they may entirely occlude the isthmus of the fauces; the half arches and posterior border of the soft palate are reddened and somewhat swollen. The surface of the tonsils is often covered with small, yellowish points, which closely resemble patches of false membrane, but careful inspection will show that they are beneath the mucous membrane, being only the distended follicles of the gland. The mucous membrane of the fauces and pharynx is more or less red and swollen.

Symptoms. Oaset more or less sudden, with rigors, rise in temperature 102° to 104° F., full, frequent pulse, 100 to 120, headache, thirst, pain and swelling at the angle of the jaw, with a constant desire to clear the throat, difficult and prinful deglutition, from the enlarged tonsils almost closing the fauces, when the respiration is more or less impeded; the voice is more or less muffled, and attempts at phonation increase the pain.

Darting pains along the Eustachian tubes are of frequent occurrence, the patient complaining of *earache* and more or less *deafness*.

If suppuration be imminent, the throat becomes more painful, the character of the pain throbbing, the febrile phenomena increase, with more or less depression, the symptoms seeming to be of great danger, when suddenly, after an effort at vomiting, or spontaneously, the tonsillar abscess bursts, a quantity of pus escapes from the mouth, and prompt relief follows.

Duration. The disease lasts from three to seven days, terminating either by suppuration or the gradual resolution of the enlarged glands.

Diagnosis. Tonsillitis can hardly be mistaken for any other affection if the fauces are inspected.

Prognosis. In the majority of cases the result is favorable, it very rarely proving fatal, except in children, and only then by obstructing the respiration, and, at the same time, so seriously interfering with nutrition that the child's strength fails.

Treatment. The first indication in an attack of acute tonsillitis, is a prompt and efficient purgative and none is better than calomel (B. Hydrarg, chlor, mitis, gr. v; sodii bicarbonatis gr. v, M., ft. chart.,

followed in six or eight hours by a saline). I can confidently recommend *sodii salicylas*, gr. x-xv, every three hours until a drachm and a half to two drachms are administered. It should be well diluted. *Salol*, gr. x, every four hours, is often a valuable remedy.

Should the febrile reaction be high, tinctura aconiti in small doses frequently repeated, either alone or alternating with sodii salicylas, rapidly reduces the temperature and the frequency of the pulse, and, by its local action, lessens the pain and swelling. If from any cause the internal use of aconitum be contraindicated, the tinctura aconiti may be diluted with glycerinum and painted over the affected parts.

Cases not seen until two or three days after the onset are benefited by the following:—

This palatable mixture, suggested by Dr. Bosworth, acts as a local astringent in passing over the inflamed tonsils, and should not be followed with water or food for an hour at least.

Scarification, a long, sharp bistoury being used to make five or six cuts, affords great relief when the tonsils are much inflamed; the external use of ice over the site of the glands, and small pellets allowed to dissolve in the mouth, afford great relief. If the application of cold be objectionable, heat may be substituted in the form of warm compresses or poultices.

In all cases we must also have recourse to such general therapeutic measures as are calculated to guide the morbid action to a favorable issue; the bowels should be kept open and the skin and kidneys active; the *diet* should be in the shape of gruels, as it is impossible for the patient to swallow any solid substance, and in cases where even gruels cause painful deglutition, thin oatmeal gruel can be used with advantage.

When suppuration cannot be averted, hot applications should be applied to the angles of the jaws, hot gargles and the steam atomizer resorted to, medicated with opium, belladonna, benzoin, or cocaine, and as soon as fluctuation can be detected the abscess should be opened. Also during this stage administer quininæ sulphas, gr. iij-v, every three or four hours. After the acute symptoms have subsided,

assist the return of the glands to their normal condition by the topical application of *cupri sulphas* (gr. xx-aquæ f3j) or *liquor ferri sub-sulphatis* (f3j-aquæ f3j).

DISEASES OF THE LARYNX.

ACUTE CATARRHAL LARYNGITIS.

Synonyms. Catarrhal laryngitis; "sore throat."

Definition. An acute catarrhal inflammation of the mucous membrane of the larynx; characterized by feverishness, diminished or suppressed voice, painful deglutition, and more or less difficulty of respiration.

Causes. Atmospherical changes; cold draughts of air, whether directly inspired or exposure of parts or all of the body to the same. Cold, wet feet; inhalation of irritating vapors, such as gas, smoke, or ammonia; inhalation of dust. Prolonged efforts at public speaking or singing or the same efforts under difficulties. In children, from violent fits of crying.

Pathological Anatomy. In mild cases there is a transient congestion (hyperæmia) of the mucous membrane over the entire, but more commonly circumscribed portions of the larynx, with more or less swelling and diminished secretion; the mucous membrane soon returns to its normal condition, the secretion being slightly increased.

Symptoms. The attack begins rather suddenly with a feeling of dryness, rawness, and tickling, referred to the larynx with the sensation of the presence of a foreign body in the throat, and with hoarseness and a disposition to cough. Deglutition causes pain by the upward movement of the larynx and by the pressure of the food on the larynx as it passes along the gullet. Attempts at speaking are attended with more or less distress and the larynx is tender on pressure.

Coughing, from the onset, of a noisy, harsh, hoarse, or toneless character and the act of coughing attended with a sensation of scratching in the larynx. The first day or two there is scanty expectoration, but in a short time the secretion is increased, giving the

cough a loose character. In the early stages the sputa may be slightly streaked with blood. Rarely a hemorrhage occurs from the mucous membrane of the larynx. The voice is at first decidedly hoarse, soon followed by complete aphonia. The respiration is but slightly, if at all, affected in adults. There may be more or less febrile reaction. In children the onset is with fever, white coated tongue, frequent, tense pulse, hot skin and flushed face, embarrassed respiration, the voice hoarse and whispering, with harsh, ringing, croupy cough and great restlessness. During the night the child is subject to suffocative attacks (laryngismus stridulus).

Laryngoscopic appearances. These vary with the severity of the attack and the stage of the inspection. In mild cases, at an early period, the mucous membrane presents a bright red appearance. Severe cases present, in addition to the bright redness, the mucous membrane swollen, to such an extent at times as to conceal the vocal cords, they appearing only as slender threads of a reddish tint. At times the mucous membrane presents the appearance of erosions or ulcerations, due to a desquamation of the epithelium.

Duration. Usually about one week; if very severe, two or three weeks may elapse before the larynx returns to its former condition.

Prognosis. Simple catarrhal laryngitis never terminates fatally. Treatment. Confinement to an apartment of uniform temperature, the air kept moist by the vapor of water being disengaged in it, and particularly in the case of children.

Locally, a hot pack should be kept constantly wrapped about the throat, and if its application is preceded by the temporary use of a weak mustard plaster, the relief afforded is more rapidly obtained. At the very beginning of an attack the feet should be placed in a hot mustard foot bath, and either a saline cathartic or mercurial purgative administered.

Prompt action on the skin at the very onset will frequently shorten the duration of a catarrh of the larynx. Use for this purpose in adults pulvis ipecacuanhæ et opii (gr. iij) combined with potassii nitras (gr. iij) every three or four hours. If there be much febrile reaction, benefit follows the use of tinctura aconiti, \mathfrak{m}_j -ij, every half hour until five or six doses are taken, after which every hour or two, combined with tinctura opii, \mathfrak{m}_j -v; or diaphoresis may be produced by antimonitiet potassii tartras, gr. $\frac{1}{20}$ - $\frac{1}{30}$, every hour, or by a hypodermic injection of pilocarpinæ hydrochloras gr. Y_3 .

For children,	several doses of the	following powder a	couple of
	the bowels are freely		

R.	Hydrargyri chloridi	mitis,		٠		٠		gr. 1	8
	Pulvis ipecacuanhæ,		٠		۰			gr. 1	8
	Sacc. lac.,						٠	gr. 1]	

to be followed by the following:-

R.	Potassii citrat.,								· Div
	Tinct, aconiti.								. m1v
	Tinct. opii camphorat.,			٠	٠			0	. 13 ij-1v
	Syr. scillæ,	٠.				•	•	٠	. 131) M
	Syr. tolu,	ad	0						. 1311J. M.

SIG.—One teaspoonful every two hours.

If a tendency to spasm of the glottis obtains, full doses of the *bro-mides* should be administered at once.

Inhalations from the onset are not only soothing, but curative, in their actions. Either of the following are recommended:—

R.	Infusi humuli, Vinegar,						. Oj . f 3 ss– j .	м.
	-Inhale hot every							

The local application of cocaine is of great benefit.

Attacks of acute laryngitis occurring from efforts in public speaking or singing are wonderfully benefited by the use of acidum nitricum dilutum, mij-v, every hour or two.

The patient should abstain altogether from the use of the voice and

from taking food or drink of an irritating character.

ŒDEMATOUS LARYNGITIS.

Synonym. Œdema of the glottis.

Definition. An acute inflammation of the mucous membrane of the larynx and that about the glottis, with an infiltration of the areolar tissue by a serous, sero-purulent or purulent fluid; characterized by obstructed or stridulous breathing and dysphonia or aphonia.

Causes. The result of acute laryngitis; abscess in or about the throat or tonsils; erysipelas of the face; scarlatina; smallpox; Bright's disease; syphilis of the larynx. Rare in children.

Pathological Anatomy. Infiltration into the loose connective tissue of the ary-epiglottic folds, the glosso-epiglottic ligament, the base of the epiglottis, and the inter-arytenoid space. If the true vocal cords are inflamed, their color changes, and instead of appearing white, glistening and brilliant, they are dull, grayish-red or violetred in patches. If the swelling be the result of purulent infiltration, the parts affected present a deeply congested color, with here and there spots of a yellowish hue.

Serous infiltration, sufficient to cause fatal œdema, disappears with death, leaving but slight traces to account for the formidable symptoms.

Symptoms. The onset is much the same as a simple catarrhal laryngitis with a gradually increasing impediment to the respiration. The patient experiences the sensation of a foreign body in the throat. and after a short time a difficulty of breathing, which ultimately threatens suffocation. The deglutition is rendered difficult owing to the swelling of the epiglottis; the voice, at first muffled, gradually becomes weaker and weaker, until finally it is almost extinct; the cough at first is dry and harsh, but as the infiltration increases it becomes stridulous and suppressed; there is no expectoration except that after great effort to clear the throat, a little frothy mucus is raised. The difficulty of respiration, as the disease progresses, becomes greater and greater, and the paroxysms of impending suffocation more frequent. The inspiration is accompanied by a whistling sound, characteristic of the narrow condition of the glottis, the patient sits up in bed, his mouth open, gasping for breath, his eyes protruding, the whole body trembling with intense convulsive movements, and after a time a general cyanosis commences, the face assuming a bluish hue, all these symptoms continuing for a few moments, when slight relief occurs, to be again followed by another paroxysm, in one of which, if nature or art does not afford prompt relief, death occurs from asphyxia.

A physical examination of the parts may be made by gently passing the finger into the throat, when the epiglottis may be felt very much thickened, and the ary-epiglottic folds may have attained such tumefaction as to convey to the finger an impression similar to that which is given by touching the tonsils.

Laryngescopic appearance. The mucous membrane has a bright red appearance. The epiglottis has the appearance of a semi-trans-

parent roll-like body, or it is often merely erect and tense. It is this condition of the epiglottis which explains the pain and difficulty in deglutition. Rarely the vocal cords are infiltrated.

Diagnosis. Any disease which gives rise to dyspnœa may simulate ædematous laryngitis, but the history of the case together with a laryngoscopic examination will generally furnish conclusive evidence as to the real nature of the malady.

Prognosis. As a rule, unfavorable. If early and vigorous treatment be instituted, recovery is possible, but without it death is the inevitable result, the patient dying asphyxiated. Even when local measures have removed the obstruction to free respiration, the patient is very likely to perish subsequently from exhaustion, or blood poisoning, or from pneumonia or other lung complication. The duration of infiltration of the larynx varies from a few hours to several days.

Treatment. Prompt local treatment must be adopted in order to remove the laryngeal obstruction. *Leeches* placed over the sides of the larynx in mild cases may effect so much reduction in the ædema as to render the subsequent progress of the case free from danger.

If the *infiltration* has already occurred and is slight in amount, scarification, guiding the instrument by the index finger of the opposite hand, may afford relief, or the hypodermic injection of pilocarpina hydrochloras, gr. 1/3, repeated, may lessen the swelling.

Niemeyer recommends the *persistent* use of small pellets of ice swallowed or held far back in the mouth till dissolved, early in the attack. Trousseau recommends the *inhalation* or *spray* of a strong solution of *acidum tannicum*. Prof. DaCosta suggests the application, as near the seat of the disease as possible, of *liquor ferri subsulphatis* (Monsel's solution), full or half strength. Mackenzie says the patient should be kept constantly under the influence of *potassii bromidum*.

If these means fail, *tracheotomy* is indicated; in those cases of sudden and rapid infiltration of the glottis or larynx occurring in Bright's disease, erysipelas, scarlatina, or syphilis of the larynx, and especially the former and the latter, *tracheotomy should be performed at once*.

In all cases of infiltration of the larynx stimulants should be boldly administered per rectum, if stomachic administration be impossible.

If the infiltration be composed of pus, quininæ sulphas., gr. v, every four hours, and stimulants are indicated.

SPASMODIC LARYNGITIS.

Synonyms. Spasmodic croup; false croup; catarrhal croup; child crowing.

Definition. A catarrhal inflammation of the mucous membrane of the larynx, associated with *temporary spasmodic contraction* of the glottis; characterized by paroxysmal coughing, difficulty of breathing and attacks of threatening suffocation.

Causes. Atmospherical changes or "taking cold"; excesses in eating and drinking; excitement; violent emotion, are all given as causes for simple croup.

Pathological Anatomy. Congestion of the mucous membrane of the larynx, with slight swelling and deficient secretion, are the

only changes that have thus far been noted.

Symptoms. The attack occurs chiefly during the *night*, the child on retiring having either its usual health, or perhaps being a little feverish. After several hours of sleep the child is *suddenly awakened* by a *paroxysm of suffocation*, and a *dry, harsh, ringing cough*. After half an hour or an hour or two the breathing becomes easier, the cough less "croupy," the skin is covered with more or less perspiration, and the child falls asleep. The next day there is present cough of a loose character, the respiration being about normal. If no treatment be instituted, the same phenomena occur on the second night, the child being apparently well during the second day, the cough being less in amount; phenomena of a similar character, but of much less severity, are present the third night, after which the disease usually disappears.

If the symptoms of the first paroxysm continue pronounced for two or three days, there is a strong probability that the inflammation may become fibrinous in character, or that true croup may develop.

Diagnosis. The symptoms are so characteristic that it seems impossible for the affection to be mistaken for any other disease.

Prognosis. Spasmodic or simple croup always terminates favorably.

Treatment. During the paroxysm, the child should at once be placed in a hot bath and hot or cold compresses wrapped about the throat. These means should be preceded or followed by a mild emetic. The late Chas. D. Meigs always used aluminis, with or without syrupus ipecacuanhæ; Prof. Bartholow recommends hydrargyri

subsulphas flavus (turpeth mineral), gr. i-iij; Prof. DaCosta suggests the cautious use of apomorphinæ hydrochloras, gr. $\frac{1}{10}$, hypodermically. A favorite remedy for emesis, in Germany, when the jaws are not closed, and one that is highly successful, is tickling the fauces with the finger or a feather until vomiting is produced. Inhalations of chloroformum often at once relieve the spasms, but must never be employed by non-professional persons. Having by any of the above means broken up the spasm of the larynx a prompt cathartic should be administered, (R. Hydrargyri chloridi mitis, gr. ij, sodii bicarbonatis, gr. iij. M. et ft. chart. No. 1), followed in six to eight hours if not sufficient results, with oleum ricini, after which:

CROUPOUS LARYNGITIS.

Synonyms. Membranous croup; true croup.

Definition. An acute inflammation of the mucous membrane of the larynx, attended with the exudation of a tough secretion—the false membrane—and the occurrence of spasm of the glottis; characterized by febrile reaction, frequent ringing cough, dyspnæa, with loud inspiratory sound, and altered or extinct voice, showing a strong tendency toward death by asphyxia.

Causes. A disease of childhood, most common in strong, vigorous, well-nourished males. Certain families present a strong hereditary tendency. Most common during a humid winter.

We cannot assent to the dictum of some authorities, that laryngeal diphtheria and croupous laryngitis are identical.

Pathological Anatomy. Intense hyperæmia of the mucous membrane of the larynx, associated with swelling, ædema and marked redness. There soon appears on the surface of the mucous membrane a grayish pellicle, rapidly coalescing and becoming thicker—the opaque, false membrane—which differs in extent, thickness and adhesiveness in different portions of the larynx. In all cases the false membrane is found on the vocal cords and inner surface of the epiglottis. The first exudation (membrane) softens by the serum

which is exuded, and is then mechanically dislodged by acts of coughing or vomiting, but is followed by successive deposits upon the mucous membrane.

When the false membrane is detached the mucous membrane of the larynx is found unaffected, so far as the loss of structure is concerned. Several successive crops of membrane may occur after the detachment, or it may entirely cease to form after the removal of the first exudation.

On microscopical examination the false membrane is found to be composed of a fine network of fibrillæ, holding in their interstices leucocytes of an albuminous or fibrinous nature.

The false membrane may extend into the pharynx, but especially is it liable to extend into the trachea and bronchial tubes, and, as the inflammation extends downward, the character of the exudation changes from fibrinous to muco-purulent.

Symptoms. The onset of "true croup" is either suddenly, by an attack of spasmodic croup, or gradually, as an acute catarrh of the larvnx, rapidly increasing in severity, with a feeling of heat in the throat, huskiness of the voice, harsh cough, fever and thirst, the hoarseness soon becoming marked, and the cough having a metallic, "croupy" character, rapidly changing to a stridulous, husky sound; every few minutes the child takes a sudden, deep stridulous inspiration, the voice becoming more and more husky. Difficulty of breathing now follows, the child is unable to lie down, or if, exhausted by the efforts at inspiration it is quiet for a moment, it soon starts up in fright, breathing more heavily, with a shrill, whistling inspiration. Soon, from the narrowing of the glottis, from the presence of the membrane, the expiration becomes difficult and noisy, and suffocation seems imminent from the paroxysmal attacks of spasm of the glottis, the child tosses wildly about, tears at its throat, as if to remove some obstacle, the face becoming cyanosed, the alæ of the nose working rapidly, the mouth wide open, the inspiratory efforts gasping, the body covered with a profuse sweat, and death seems imminent, when, suddenly, the spasm is relaxed, air enters the chest, the breathing becomes somewhat easier, and the child, exhausted and partially stupefied, drops into a fitful sleep of a few moments' duration.

The suffocative attacks return at short intervals, or there occur decided remissions between them, considerable portions of the false membrane being expelled, allowing the child to fall into a refreshing sleep.

In those cases which tend to a favorable termination, the appearance of improvement noted between the suffocative attacks is maintained, the paroxysms of suffocation becoming less frequent, the expectoration of membrane more marked, the difficulty of breathing lessens, the cough loosening, the voice gradually returning, the fever, which has been more or less high during the attack, disappearing.

If, instead of improvement, the case tends toward a fatal termination, the suffocative attacks become more frequent, expectoration is absent, the voice and cough inaudible, although the efforts at speaking and coughing are visible, the difficulty of breathing continues, the respirations becoming more frequent and shallow, but without whistling and stridor, cyanosis deepens, the countenance has an indifferent, drowsy and stupid look, the eyes dull and nearly closed, with symptoms of depression, the pulse rapid and weak, the surface covered with a cold, clammy sweat, the extremities cold, stupor and insensibility more marked, the child dying of carbonic acid poisoning or asphyxia.

Duration. The duration of true croup is about one week, rarely continuing ten days.

Diagnosis. *Œdema of the glottis* might be mistaken for croup until the period of the formation of the characteristic membrane. The chief points of distinction from the onset are, however, absence of fever, paroxysmal attacks of difficult respiration, followed by a complete return to the normal condition. Œdema of the glottis is rare in childhood.

The following are the chief points of difference between croup and laryngeal diphtheria:—

CROUP.

A local disease.

Begins in trachea and extends up. Exudation never cutaneous.

No pain in swallowing.

No swelling of sub-maxillary and lymphatic glands.

Cough always present and often reduced to a mere whistle with peculiar metallic ring.

Not traceable to bad drainage.

DIPHTHERIA.

A constitutional disease.

Begins at tonsils and extends down.

Exudation often cutaneous.

Often severe pain in swallowing.

Swelling of submaxillary and lymphatic glands.

Seldom much cough and then only hoarse.

Often traceable to bad drainage.

CROUP.

Seldom occurs in adults.

Neither contagious nor infectious.

A sthenic disease.

Membrane does not extend to nares.

No symptoms of septicæmia,

No albuminuria.

Neither attended with nor followed by paralysis.

Death seldom caused by syncope.

Death due to suffocation.

Absence of a specific germ.

DIPHTHERIA.

Often occurs in adults.

Both contagious and infectious, both before and after death.

An asthenic disease.

Often extends to nares and many other parts.

Septicæmia generally present.

Albuminuria frequent.

Paralysis not uncommon.

Death from syncope common.

Death frequently results from other

causes.

Presence of the Klebs-Læffler bacillus.

Prognosis. A very fatal disease. The danger increases in proportion to the age and feebleness of the child.

Unfavorable symptoms are: Loud, stridulous, inspiratory and expiratory sounds, laborious and prolonged expiration, depression of the base of the thorax during inspiration, whispering voice or complete aphonia, congestion of the face and neck, stupor, weak, rapid and irregular pulse, cold extremities, and a cold, clammy perspiration.

Favorable symptoms are: Expectoration of false membrane, decrease of the stridulous respiration, voice changing from whispering to hoarseness, looseness of the cough, moderation of the fever, and an improvement in the general condition.

Treatment. The indications for treatment are to detach and remove the false membrane, to prevent its reformation, to prevent the attacks of spasm of the glottis, and to maintain the strength.

To detach and remove the membrane *emetics* are of the highest utility, the favorite of this class being the one first used in this disease by Dr. Fordyce Barker, consisting of *hydrargyri subsulphas flavus* (turpeth mineral), gr. ij, for a child of two years of age, repeating the dose as often as rendered necessary by the obstructed breathing; but the unnecessary administration of emetics should be avoided, as the strength of the patient must be maintained.

To prevent the formation of the membranous exudation a number of remedies have been recommended and highly lauded, but

hydrargyrum is the only one that has stood the test of experience; it may be used as hydrargyri chloridum corrosivum, gr. $\frac{1}{48}$ - $\frac{1}{24}$, every two or three hours, or in the following formula:—

R. Hydrargyri chloridi mitis, gr.
$$\frac{1}{2}$$
 Sodii bicarbonatis, gr. ij Pulvis ipecacuanhæ, gr. $\frac{1}{12}$ M.

Sig.—One powder every two hours.

Prof. DaCosta has suggested either of the following combinations:

Or-

Antimonii et potassii tartras, a remedy that some years ago was popular in large doses, is again brought forward in doses of gr. $\frac{1}{30} - \frac{1}{20}$. Quininæ sulphas, gr. v, every three hours until six doses have been taken, if given before the exudation has formed, it is claimed will prevent its formation. It can be used by suppository.

To prevent the paroxysms of spasm, small doses of opium in the form of pulvis ipecacuanhæ et opii (Dover's powder), or full doses of the bromides, preference being given to ammonii bromidum, as suggested by Prof. Bartholow, on account of its being "eliminated by the bronchial and faucial mucous membrane, thus acting locally."

To maintain the strength of the patient, alcoholic stimulants in full doses, nutritious but easily digested aliment, quinina in tonic doses, and ammonii carbonas, are particularly indicated.

Locally, the use of all caustic or irritating applications to the fauces or larynx is emphatically contraindicated.

The *inhalation* of the vapor of slaked, freshly burned lime is one of the most ready and efficient means for assisting in the detachment of the false membrane. The application of *cold or hot compresses*, according to the feelings of the patient, around the throat, have a strong tendency to prevent the recurrence of the spasms. After the formation of the membrane, great relief follows the use of the vapor inhalations and of oxygen gas, which with stimulants and liquid nourishment may safely carry the patient through the disease. Cases

in which the membrane presents a tendency to slowly loosen itself, if the patient's strength does not contraindicate it, are greatly benefited by the application of *sinapis*, or even small *flying-blisters*, to the larynx. Inhalations of *oxygen* have seemed useful in several cases, as has the internal use of *hydrogen dioxidum*.

Niemeyer advises in cases showing carbonic acid poisoning from obstruction of respiration due to accumulation of membrane, the pouring from a moderate height of a few gallons of cold water over the head, nape and back of the child; the shock produced always causes it to revive for a while, and to cough vigorously, thus expectorating large quantities of the membrane.

Relief from the obstructed respiration is obtained and the affection often beneficially influenced by the use of "O'Dwyer's tubes."

If the exudation still continues, regardless of the means employed, the propriety of *tracheotomy* must be determined.

LARYNGISMUS STRIDULUS.

Synonyms. Spasm of the glottis; pseudo-croup; Millar's asthma; thymic asthma; "Kopp's asthma;" tetany.

Definition. A spasm of the muscles of the larynx innervated by the inferior or recurrent laryngeal nerves; characterized by a sudden development of dyspnæa and the appearance of deficient oxygenation of the blood.

MacKenzie describes it as "a form of convulsion occurring in ill-nourished infants, characterized by spasmodic action of the abductors of the vocal cords, and in severe cases by spasm of the diaphragm and intercostal muscles."

Causes. Most common in children, the result of teething, laryngitis, indigestion, scrofula, or other cachexiæ. Attacks in adults are not uncommon. It is often hereditary.

Pathological Anatomy. Death the result of spasm of the glottis is such a very rare occurrence that the changes in the larynx are illy understood.

The mechanism consists in an irritation of the superior laryngeal nerve—the afferent nerve—whose function is to supply the mucous lining of the larynx with sensibility, whence is reflected through the inferior laryngeal nerve—the efferent nerve—the motor influence resulting in the spasm of the laryngeal muscles.

Symptoms. The spasm of the laryngeal muscles is of sudden onset, and usually after nightfall. The child may have been in perfect health, to all appearances, on retiring, or it may have shown symptoms of catarrh of the upper air passages, or been suffering from gastro-intestinal or dental irritation.

The child awakes suddenly, coughing in a metallic, resonant tone—the croupy cough—and with great dyspnæa, with loud, crowing, stridulous inspirations, the result of narrowing of the larynx from spasm, with wheezy, stridulous expirations.

The entrance of air is so greatly obstructed that all the accessory muscles of respiration are called into use; the lips and finger nails become blue, the surface cold, the countenance anxious, and the inferior portion of the chest is drawn in, instead of being expanded, during inspiration. General convulsions occur at times, during a paroxysm, also strabismus, and involuntary discharge of the fæces and the urine.

The paroxysm continues from half an hour to an hour or more, to return after a few hours' sleep, or during the following night; the cough, during the day, having the croupy character.

Diagnosis. The non-febrile and distinctly intermittent nature of the affection differentiates it from croup, and its own distinctive characters, from all other diseases. The view is gaining that it is a variety of tetany.

Prognosis. Favorable. Death from suffocation during the paroxysm may occur in very young children, but it is certainly a very rare termination.

Treatment. For the paroxysm, the inhalation of a few drops of chloroformum is the most prompt method, due care being exercised, as complete anæsthesia is unnecessary. Success is reported from the prompt inhalation of amyl nitris, also from nitro-glycerinum, in small, but frequently repeated doses. The following combination is a prompt antispasmodic:—

Ŗ.	Potassii bromidi,		,					٠	٠	٠				3 ij
	Chloral,	0			۰		0			9		۰	0	gr. xxxii
	Syr. aurantii cort.,			٠			0	0		0				fŽj
	Aquæ menth.,	0	0	0			0	0	0	۰	0		0	f3j.
Stg.	One teaspoonful	V G	21.37	h	1f	he	3111							

After the paroxysm has been suspended by the above combination, the tendency to a recurrence of the attacks is prevented by the steady and continued use of *potassii bromidum*, in moderate doses. *Emetics* are often useful in suspending an attack, especially if it be due to indigestion.

Mackenzie advises the use of *musk* during the attack if the child can swallow; and if not, then as soon as the child can take it, and continued at intervals for a day or two. His formula is as follows:—

Ŗ.	Moschi,				٠		٠	٠			. gr. iss	
	Sacch. alb.,	٠	٠	۰	٠				۰	٠	. gr. ij	
	Pulv. acaciæ,											
	Syr. aurantii flor.,											
	Aquam,		äā	٠		ad			٠	٠	. fġj.	M.
SIG.	—A dose.											

The high price of musk prohibits its general use.

Locally, the hot, alternating with the cold pack, should be constantly applied to the throat.

The air of the room should be moistened by the vapor of hot water constantly disengaged in it.

After the attack has passed off, the general condition of the child requires attention; for this purpose it is well to administer a dose of hydrargyri chloridum mite, to be followed by a dose of oleum ricini or magnesii carbonas. The diet must be regulated, all farinaceous articles being absolutely forbidden.

TUBERCULOUS LARYNGITIS.

Synonyms. Laryngeal phthisis; throat consumption.

Definition. An inflammation, tending to ulceration, of the tissues of the larynx, of tuberculous origin; characterized by pain on deglutition, cough, weakness of voice, and progressive emaciation, associated with hectic fever.

Causes. An infection of the larynx with the bacillus tuberculosis, either from the inspired air or by the sputum. A depressed state of the system is essential for the action of the bacilli.

Pathological Anatomy. It is well to remember that all chronic inflammations of the larynx associated with pulmonary tuberculosis are not tubercular.

Begins with redness of the mucous membrane, showing scattered tubercles. The tubercles show a strong tendency to cluster, then soften, leaving shallow irregular ulcers. The ulcers are covered with

a grayish exudate. The mucous tissue round about the ulcers is thickened. The ulcers may and generally do, erode the true vocal cords, often entirely destroying them. The ulcers slowly extend in all directions, destroying the tissues attacked. The epiglottis may be entirely destroyed.

Symptoms. Usually develops secondary to pulmonary symptoms; rarely it may occur as a primary disease to be followed with tuberculosis of the lungs. The first symptom is a change in the voice—huskiness; this associated with symptoms of ill health is always a warning to the physician. The husky voice may proceed until it is but a painful whisper. Cough of an irritating painful character associated with slight expectoration. Painful and difficult deglutition (dysphagia) is a very constant and distressing symptom. There is the remitting fever so characteristic of tuberculosis, with night sweats, loss of appetite, loss of flesh, and insomnia.

Laryngoscopic examination reveals the characteristic broad, shallow, irregular, grayish ulcers, with the thickened surrounding mucous membrane. The vocal cords show infiltration and thickening or ulceration.

Diagnosis. To discriminate from non-tubercular laryngitis, examine the sputum and if the specific bacilli are found the diagnosis is conclusive.

Prognosis. Unfavorable.

Treatment. Remember that tubercular laryngitis is not always preceded by pulmonary phthisis, but in a fair proportion of cases is a primary disease. Much can be done to make the patient comfortable. The application of twenty, forty, or even sixty, per centum solution of acidum lacticum is a very successful remedy, Cocaina hydrochloras applied directly to the ulcers gives relief to the pain and dysphagia. Local applications of hydrogen dioxidum, argentinitras, and menthol are of value. Curetting the ulcers and applying iodoformum in emulsion or with morphina sulphas has been practiced with benefit.

The general condition must be treated, the diet liquid and of a most nourishing character.

DISEASES OF THE BRONCHIAL TUBES.

ACUTE BRONCHITIS.

Synonyms. Bronchial catarrh; acute bronchial catarrh; "cold on the chest."

Definition. An acute catarrhal inflammation of the bronchial tubes of the larger, middle and third size; characterized by fever, sub-sternal pain, a feeling of thoracic constriction, oppression in breathing, and at first scanty, followed by more or less profuse expectoration.

Causes. Most frequent in childhood, especially during the period of dentition, when there exists a strong tendency to catarrh of the mucous membranes in general and of the bronchi in particular. In old age the predisposition again returns. Inhalations of irritants such as dust, smoke and air too hot or too cold. More common in climates characterized by considerable moisture of the atmosphere combined with a low temperature, and especially where there are sudden and marked variations.

Pathological Anatomy. Hyperamia of the mucous membrane of the bronchial tubes, manifested by a diffused redness, swelling, adema and diminished secretion; this is followed by an increased secretion and overgrowth and desquamation of the epithelial cells, together with a copious generation of young cells, the expectoration then becoming of a yellowish color (muco-purulent). As a result of the hyperamia, rupture of the capillaries of the mucous membrane frequently occurs, when the slight expectoration of the first stage is streaked with blood.

In cases of bronchitis following the exanthemata, or in scrofulous patients, the bronchial glands participate in the inflammation, they becoming hyperæmic, swollen and filled with secretion, and not unfrequently the glandular elements undergo a hyperplasia, and finally the "cheesy" degeneration.

Symptoms. The *invasion* is usually characterized by the occurrence of either nasal or laryngeal catarrh, or both, the patient feeling *chilly*, followed by *flushes of heat*, the *limbs*, *joints*, and even the *body*, are affected with *pain* of an aching, contused character, and

with a sense of fatigue and want of energy; there may be a furred tongue, anorexia and constipation.

In nervous, irritable persons, and in children, there may be slight delirium, and often in very young children, especially during the period of dentition, convulsions may usher in an attack.

After a day or two of these initiatory symptoms, those characteristic of bronchial catarrh develop.

Pain is experienced beneath the sternum, especially towards its upper part, of a raw, burning or tearing character, aggravated by a deep inspiration or by coughing; the pain also radiates towards the sides, following the course of the primary bronchial tubes. Tenderness over the sternum is often experienced.

Cough from the onset, at first in paroxysms of a hard, dry character, changing as the disease progresses, and becoming looser, followed by free expectoration. The expectoration at first is small in quantity, almost transparent, frothy, and having a salty taste, often streaked with blood. As the disease progresses, it becomes more abundant, of a yellowish or a greenish-yellow color, and of a tenacious consistency.

There are present slight fever, hot, dry skin, frequent pulse, loss of appetite, moderate thirst and constipation.

A feeling of languor and weariness, and often considerable depression, quite out of proportion to the febrile state, are not infrequent.

Percussion. *Normal*, except in those rare cases in which the bronchial glands are involved, when irregular spots of dullness can be developed.

Auscultation. First Stage: The bronchial membrane being swollen and dry, the respiratory murmur is harsh or vesiculo-bronchial in character, associated with diffused sonorous and sibilant râles.

Second Stage: The secretion from the bronchial mucous membrane being increased, the respiratory murmur is less harsh in character, but is associated with large and small moist or bubbling râles.

Diagnosis. The points of resemblance and difference between acute bronchitis and other diseases of the chest will be pointed out when those affections are described. The association of bronchitis with other diseases must not be forgotten.

Prognosis. Acute bronchitis of the larger tubes usually terminates in complete resolution within two weeks. In children and in the aged, the course is more protracted, and the symptoms more

severe, but recovery is the rule. Very aged and feeble persons may succumb, but it is rare.

Treatment. During the *invasion*, *quininæ sulphas*, gr. x, combined with *morphinæ sulph.*, gr. 1/6, will usually prevent or abort an attack of acute bronchitis.

In the *first stage*, in adults, when the mucous membrane is swollen and dry, either of the following prescriptions will give prompt relief:—

R.	Antimonii et potassii tart.,								gr. ij	
	Liquor. ammonii acetatis, .			0				٠	f 3 iv	
	Spts. ætheris nitrosi,			۰		5	۰	۰	f℥j	
	(Tinct. aconiti, if indicated)	2			٠		٠		f z ss	
	Syr. simplicis,	۰	ad					٠	f Z vj.	M.
Sic	Two teaspoonfuls every tw									

Sig.—Two teaspoonfuls every two or three hours

Or-

Sig.—Tablespoonful every two or three hours.

If the cough of the dry stage be severe, or if looseness of the bowels follow the use of either of the above combinations, tinctura opii camphorata may be added with advantage.

For young children, the above in proportionately reduced doses, or

the following :-

Sig.-One every two hours.

Locally: Hot mustard foot bath, and sinapis or terebinthina stupes over the chest, the patient being confined to an apartment in which the air is moistened by the vapor of hot water.

Second Stage: The secretion of the bronchial mucous membrane being copious, stimulating expectorants are indicated such as ammonii chloridum, scilla, ammonii carbonas, or potassii carbonas. A reliable combination is:—

R.	Ammonii chloridi	, .	0				٥		۰			. 3 iss	
	Scillæ aceti,				0	۰		۰		0	٠	. 1311	М.
	Scillæ aceti, Misturæ glycyrrh	izæ	CO	mp).,	b	۰	٠	ad	۰		. 1 3 mJ.	٠,١٠

Sig.—Dessertspoonful every three hours.

Attacks showing a tendency to linger are greatly benefited by the following:—

R.	Terpini hydrat., .						, gr. xlviij
	Glycerini, Syr. lactucarii, .						
Sto	_Teaspoonful ever						***

During the attack, attention must be given to the secretions and to the diet of the patient.

CAPILLARY BRONCHITIS.

Synonyms. Broncho-pneumonia (?); "suffocative catarrh."

Definition. An acute catarrhal inflammation of the mucous membrane of the *terminal* bronchial tubes, or bronchioles; characterized by fever, impeded and increased respiration, impeded circulation, slight cough and scanty expectoration, and symptoms of non-aeration of the blood.

Causes. Most common in childhood, following exposure to cold or sudden changes of temperature; occurs also in the aged, and also complicates measles, whooping cough, or any of the debilitating diseases. There may be a special germ.

Pathological Anatomy. *Hyperæmia*, redness and swelling of the lining membrane of the bronchioles, with the exudation of a tough, tenacious secretion.

In those cases in which the air cells are not involved in the inflammatory changes, the air passes, during the act of inspiration, through the secretion blocking the smaller tubes, but is prevented from escaping during the act of expiration, the secretion in the smaller tubes acting as a valve; the result is distention of numerous vesicles, producing a circumscribed or diffused functional emphysema. If the secretion produces complete closure of any of the smaller tubes, the air previously drawn into the vesicles will be absorbed, causing collapse (atelectasis).

If the inflammation extends to the alveoli of the lungs, it produces the condition known as *broncho-pneumonia*, a frequent complication in children and feeble elderly people; it is most commonly lobular in character, whence the term "lobular pneumonia."

Symptoms. Usually preceded by more or less ordinary bronchitis, followed by *rise of temperature*, 102–103° F., increased pulse,

difficult and increased respiration, numbering forty, fifty or sixty in the minute, with paroxysms in which the dyspnœa is markedly aggravated, when cyanosis rapidly develops; the tongue is coated, bowels costive, appetite impaired, and there is restlessness and headache.

The circulation through the lungs is impeded by the dyspnæa, the pulse becomes feeble and flickering, and there results general congestion of the venous system, the countenance becomes livid, the lips and nails blue, the surface cold, and often covered with a clammy perspiration, the mind dull, and in children stupor and convulsions rapidly supervene, the result of the non-aeration of the blood. The cough is slight, but of a suppressed character, the expectoration scanty, the patient usually swallowing the sputum. When cyanosis occurs, the cough may almost entirely cease; expectoration also ceases, death soon following, from apnæa and depression.

Percussion. *Normal*, except over those portions of the lungs (a bilateral disease) which are in a condition of *collapse*, when dullness rapidly develops and may as rapidly disappear, changing to other portions of the lung—shifting dullness.

Auscultation. First stage, a feeble, but high pitched, respiratory murmur, becomes less distinct and harsh as the disease progresses. The râles in the first stage are fine whistling, sibilant, changing in the second stage to fine bubbling or subcrepitant râles. The respiratory murmur is absent over the dull area.

Diagnosis. There is one point characteristic of capillary bronchitis—it is a general or bilateral disease. Capillary bronchitis is often mistaken for true catarrhal pneumonia, the points of distinction between which will be pointed out when discussing the latter affection.

Prognosis. In children, on account of their inability to expectorate, which tends to rapid collapse of the lungs, and in the aged, the prognosis is most grave. In the strong and vigorous, recovery follows prompt and energetic treatment.

Treatment. From the very onset of the attack the treatment must be supporting, with the addition of such measures as seem to possess a controlling influence over the catarrhal process.

The patient must be confined to bed, well covered and the temperature of the room varying between 75° and 80°, the air moistened with steam. In the first stage *dry cups*, mild *sinapis* applications or *terebinthina stupes* should be applied to the chest, after which it should be covered with an oil-silk jacket or a cotton jacket.

The diet must be of the most nutritious character, the great aim being to sustain the powers of life until the catarrhal process has passed through its different stages, hence milk, eggs, chicken, mutton and beef broths, with the free use of stimulants, commenced early and in amounts large enough to overcome the signs of depression which are present early in the attack.

Unless the fever be high, 102° F., and continues, it need not be treated, but if it continues at that point or higher, a few doses of acetanilidum, gr. ij-iv, in brandy or whiskey may be used. If the urine be scanty, use spiritus ætheris nitrosi.

If suffocation be imminent, the cautious use of emetics may be indicated; the most suitable are ipecacuanha and hydrargyri subsulphas flavus. Do not repeat emesis so often as to produce exhaustion.

For the catarrhal process two remedies are of inestimable value; one is potassii iodidum, gr. j-ij, for a child every hour or two, and gr. v-x for an adult, its action being to liquefy the tenacious secretion and modify the inflammatory action; the other is ammonii carbonas, gr. j-ij, for a child every hour or two, and gr. v-x for an adult. The two combined, but for the taste, make a valuable prescription:-

Ŗ.	Potassii iodidi, .				4							gr. ij-v	
	Ammonii carbonat	۰,				à				٠		gr. iij-v	
	Syr. glycyrrh., .								٠		. 1	3 ss	
	Syr. tolu,		٠	٠		٠		۰			. 1	[3 ss. '	M.
Sic	Every two or thre												

Sig. - Every two or three hours,

Excellent results have been obtained in the children's wards of the Philadelphia Hospital from the careful inhalation of oxygen. Prof. H. C. Wood, in desperate cases of suffocative catarrh, advises the alternate use of the hot and cold douche conjointly with stimulating remedies.

FIBRINOUS BRONCHITIS.

Synonyms. Membranous bronchitis; plastic bronchitis; diphtheritic bronchitis: croupous bronchitis.

Definition. An acute inflammation of the mucous membrane of the larger and middle-sized bronchial tubes, attended with an exudation, forming a membraniform layer, which is closely adherent to the mucous surface; characterized by febrile reaction, cough, difficult breathing, scanty expectoration, followed by the expulsion of the false membrane in the form of patches or casts.

Causes. Unknown; associated with membranous laryngitis from extension downward; asthma; emphysema; phthisis; frequently result of exposure to cold or damp, in those of feeble health or in tuberculous (?) constitutions.

Pathological Anatomy. Hyperamia of the mucous membrane of the bronchial tubes, associated with swelling and adema, during which the surface is covered with a whitish or grayish-white, firmly adherent, membranous deposit, cemented together by a coagulable exudation, and prolonged by rootlets from its under surface into the bronchial follicles, which sooner or later is loosened and detached by suppurative process and is expectorated after a violent fit of coughing or vomiting. When expectorated, the false membrane, as it has been termed, has either the form of patches or is thrown off entire from the bronchial tube, and may be found to consist of casts representing more or less of the bronchial subdivisions, and presenting an appearance not unlike "boiled macaroni."

On *microscopical examination*, the detached membrane presents fibrillæ which characterize fibrin or lymph in other situations, and if placed in a solution of acetic acid, it becomes greatly swollen, while ordinary mucus contracts and becomes more dense if added to the same solution.

Symptoms. There are no symptoms or signs by means of which this variety of bronchitis can be distinguished from ordinary catarrhal bronchitis, *prior to the expectoration of the false membrane*.

Expectoration is preceded and accompanied by violent paroxysms of coughing, and after more or less of the membrane has been raised a muco-purulent expectoration, streaked with blood, may be present for several days.

Duration. The inflammation may be either *acute*, *sub-acute*, or *chronic*, expectoration of patches or strips of the membrane being repeated at intervals of days, weeks, months, or even years.

Prognosis. In adults, favorable, if not associated with other grave affections, such as phthisis, pneumonia, or emphysema. In young children it may cause obstruction to the respiration, and not unfrequently proves fatal.

Treatment. As the character of the inflammation can seldom be determined until the membrane or portions of it have been expectorated, the treatment is at first the same as in cases of ordinary acute bronchitis. As soon, however, as the character of the inflammation can be determined, active *emesis* is the most effective means of removing the obstruction caused by the false membrane, the best agents of this class being either *hydrargyri subsulphas flavus*, *ipecacuanha*, or *zinci sulphas*, to be repeated as indicated.

Inhalations of solutions of ammonii chloridum, pix liquida, euca-lyptol, or simply the vapor of water, and especially of lime water, are highly serviceable.

To prevent the formation of membrane, Prof. Bartholow strongly urges the use of *ammonii iodidum* and *ammonii carbonas* combined, in small doses, every hour or two. In a case treated by the author after this method, excellent results followed. *Potassii iodidum* is also useful

In cases showing a tendency to become chronic, good results will follow the application of flying *blisters* to the chest and the internal administration of *arsenicum* and some preparation of *pix liquida*.

CHRONIC BRONCHITIS.

Synonyms. Chronic bronchial catarrh; winter cough; secondary bronchitis. In the aged, senile bronchitis.

Definition. A chronic inflammation of the mucous membrane of the larger and middle-sized bronchial tubes; characterized by cough and more or less profuse expectoration, plus, in many cases, the symptoms of *emphysema* of the lungs, which is a frequent complication.

Chronic bronchitis may be either primary or secondary.

Causes. *Primary*, exposure to wet or cold, or the repeated inhalation of dust, vapors, or other irritants. *Secondary*, gout, rheumatism, syphilis, cardiac, renal, or pulmonary diseases, or alcoholism.

Varieties. I. Mucous catarrh, associated with moderate expectoration. II. Bronchorrhwa, profuse expectoration. III. Dry catarrh, scanty expectoration. IV. Fetid bronchitis. V. Bronchiectasis, or dilatation of the bronchi.

Pathological Anatomy. The mucous membrane of the bronchial tube is discolored, being of a more or less dull red, often of a deeply venous hue, mingled with a grayish or brownish color. These changes may be either in patches or extensively diffused. The vessels of the mucous membrane are dilated. The mucous membrane

is thickened, resulting in the reduction in the calibre of the tube and a roughening of its internal surface. The submucous tissue becomes infiltrated, contracted, and indurated.

The elastic and muscular coats of the tubes become hypertrophied, lose their elasticity, and the cartilages become the seat of calcareous deposits.

As the result of the loss of elasticity and muscular tone of the tubes they become irregularly dilated, "bronchial dilatation." The dilatations may be uniform in character, resembling somewhat the fingers of a glove, or they may be sacculated or globular, forming actual cavities in the bronchial structure.

In the *mucous variety* the secretion consists of young cells and mucous corpuscles, having a yellowish color; in the *dry variety*, the "catarrhe sec" of Lænnec, or "dry bronchial irritation," the secretion is scanty, tough, semi-transparent, and occurs in defined globular masses; *in bronchorrhwa*, which is usually associated with bronchial dilatation, the secretion is abundant, greenish-yellow in color, and often fetid.

The majority of cases of chronic bronchitis have associated chronic gastric catarrh.

Symptoms. The most characteristic symptoms of chronic bronchitis are the *cough* and *expectoration*. The cough occurs at all hours, but is more severe at night and early in the morning. The cough is not always present. It disappears almost altogether for a time, and then reappears, continuing thus for years. Coated tongue, disagreeable taste, loss of appetite, impaired digestion, with eructations of gases, are present in many cases, due to the chronic gastric catarrh. Unless associated with other diseases, the general health suffers but little, if at all, constitutional symptoms being present only during acute exacerbations.

Mucous catarrh, or, from its occurring most commonly during the winter months, "winter cough," is characterized by paroxysms of cough, more or less violent, followed by the expectoration of a yellowish mucus.

Dry catarrh is characterized by a harsh cough, a feeling of soreness or rawness under the sternum, and the expectoration of small globular masses; this variety occurs with emphysema, gout, rheumatism, and asthma.

Bronchorrhaa, which is associated with bronchial dilatation, and

most common in the elderly, is characterized by paroxysms of severe coughing, followed by the copious expectoration of greenish-yellow, often fetid, mucus; the amount expectorated often amounts to four or five pints in the twenty-four hours.

Fetial bronchitis, often associated with bronchial dilatation, has an excessively fetid odor of the breath and expectoration. The decomposition of the secretion may cause gangrene of the bronchial mucous membrane, and even of the lung structure.

Percussion. Unless complicated with other affections, *normal*; if bronchial dilatation occur, there are *diffused* spots of the *tympanitic* or *amphoric* percussion sound, the physical condition being a circumscribed cavity containing air and communicating with a bronchial tube.

Auscultation. Harsh or vesiculo-bronchial respiration, associated with more or less profuse, sonorous, sibilant, and large and small bubbling râles; in bronchial dilatation, in addition to the harsh respiration, is found broncho-cavernous breathing, with large and small gurgling râles.

If *emphysema* complicate chronic bronchitis, the physical signs are somewhat modified, and will be pointed out when discussing that affection.

Diagnosis. Make it a rule to always examine the urine in case of cough, and particularly in case of chronic bronchitis, as this latter disease is one of the most common complications of Bright's disease.

Incipient phthisis is often confounded with chronic bronchitis. The diagnosis is not always easy. The physical signs of chronic bronchitis are more or less diffused through both lungs, and not, as a rule, associated with failure of the general health; while in phthisis, from the onset, there is failing health, with a concentration of the physical signs to the apices. The discovery of the bacillus determines the diagnosis.

Prognosis. If unassociated with disease of the lungs, heart or kidneys, chronic bronchitis is never dangerous to life, although the symptoms are present, more or less, continually, and aggravated upon the least exposure. Rarely is a cure recorded.

If associated with phthisis, emphysema, disease of the heart or of the kidneys, the prognosis is governed by those affections. In turn, it is to be remembered that chronic bronchial catarrh may lead to emphysema of the lungs, asthma, or to cardiac dilatation. Treatment. Cases of chronic bronchitis, of whatever variety, should observe the following general rules: 1. Attention to the general health. 2. The clothing; wearing flannel the year round, or, what is better, silk under-clothing, taking care that the opposite extreme of too much clothing be not practiced.

The medical treatment is guided by the cause, character, and severity of the disease.

If secondary to other affections, in the majority of cases remedies directed to the bronchial mucous membrane are contra-indicated. If the result of the rheumatic or gouty diathesis, in addition to the remedies directed to the disease itself, should be combined change to a warm climate, if possible, and a more or less protracted course of potassii iodidum, or lithii citras, or a residence at one of the alkaline springs.

If associated with alcoholism or chronic gastric catarrh, the following is a valuable combination: [R. Ammonii chloridi, 3iij; tinct. nucis vomicæ, f3ij; infus. gentianæ comp. ad., q. s., f3iv. M. et Sig. Dessertspoonful in water before meals.]

Sig.—Dessertspoonful every four hours.

For bronchorrhwa, copaiba, gtt. v-x every three hours, or spts. terebinthinæ, gtt. v, every four hours, or acidum carbolicum, gr. ss.

four times a day, or terebenum, m.y., or terpini hydras, gr. iij, in pill or capsule three or four times daily, and at the same time using ol. morrhuæ and arsenicum, or, if these means fail, inhalations of alumen, acidum gallicum, or acidum tannicum,

If the expectoration be fetid, "fetid bronchitis," Prof. Da Costa recommends the internal use of acidum carbolicum, gtt. j every third hour, with inhalations of acidum carbolicum (gr. v, aqua, f3j) two or

three times a day.

If, after prolonged treatment, cure or great amelioration does not occur, then a change of climate is called for. Usually a warm climate is the most suitable, but sometimes a dry, bracing climate does better.

Locally, irritation with tinctura iodi, or flying blisters, repeated once or twice weekly, is of advantage.

ASTHMA.

Synonyms. Bronchial asthma; spasmodic asthma.

Definition. A paroxysmal, spasmodic contraction of the muscular layer surrounding the smaller bronchial tubes, and perhaps associated with a tonic spasm of the diaphragm and more or less bronchial catarrh; characterized by spasmodic attacks of distressing expiratory dyspnæa, continuing several hours, days, or weeks.

Causes. A true neurosis of the respiratory apparatus. The result of peripheral or local disturbances in the nervous system. Chiefly hereditary. A family history of asthma, chorea, or epilepsy. It sometimes is of reflex origin, starting from diseases of the nasal mucous membrane, explaining the attacks due to the inhalation of various substances, as ipecac, turpentine, or irritating dusts. Climate. Some attacks may be due to a peculiar and characteristic disease of the bronchial mucous membrane—an "asthmatic bronchiolitis."

Asthma is more common in men than in women; in childhood and young adults than those of middle life and old age; in the well-to-do and wealthy than in the poor.

Symptoms. The onset of a first attack of asthma is abrupt and sudden, the succeeding attacks being preceded by prodromes, which the individual rapidly learns to appreciate, to wit: coryza, bronchial irritation, thoracic constriction, marked dyspepsia, or the scanty passage of pale, limpid urine, the "hysterical urine."

The paroxysm begins, in the majority of instances, in the early morning hours or during the afternoon, with a feeling of anguish and constriction in the chest and an intense desire for air. The breathing is accompanied with loud wheezing, the face is flushed, at times even cyanosed, and bathed in perspiration, the eyes staring, the eyeballs protrude, and the muscles of the neck become prominent as they aid in the effort for air. The dyspnæa soon becomes so severe that the inspiration is but a gasp, the lips are pallid, cyanosis deepens, and the patient feels as if death were impending. Owing to the tonic contraction of the smaller bronchi the air drawn into the alveoli escapes imperfectly, resulting in the expiratory dyspnæa, the emphysematous chest, and the lowered position of the diaphragm.

After some minutes or hours the respiration becomes easier, the air in the lungs changes, the cyanosis disappears, and gradually the paroxysm ceases, the patient feeling exhausted and the chest fatigued.

During the paroxysm there is a short, dry cough, becoming looser as the attack subsides. The *sputum* of asthma is unique. Early in the paroxysm it is raised with difficulty, and is in the form of rounded gelatinous masses ("perles" of Lænnec). If these pellets be carefully examined they will be found to consist of moulds of the smaller bronchi, and, under the microscope, show Leyden's crystals and Curschmann's spirals. After a day or two the sputum becomes muco-purulent, and the spirals and crystals are absent.

The duration of an attack varies from one to many hours, or even days. Instead of single paroxysms, slight remissions may occur at intervals of one, two, or three hours, to be followed by exacerbations lasting from four to six hours, continuing for a week or two, preventing the patient lying down or taking food.

Percussion. During the paroxysm, hyper-resonance over both lungs, termed vesiculo-tympanitic, the "band-box tone" of Bamberger, due to the retained air in the alveoli.

Auscultation. First stage feeble or absent vesicular murmur, with prolonged expiration associated with loud wheezing, whistling, sibilant and sonorous râles; as the paroxysm subsides, the vesicular breathing becomes more apparent and is associated with moist râles.

Prognosis. In itself asthma is not fatal to life; but if the paroxysms are frequently repeated there results either *emphysema*, *cardiac dilatation* with subsequent dropsy, or even cerebral hemorrhage.

Attacks of asthma frequently occur as a complication in emphysema, chronic bronchitis, valvular diseases of the heart, or Bright's disease.

Treatment. There are two indications, to wit: the relief of the

paroxysm, and to prevent its recurrence.

To relieve the paroxysm, no medication is so effective as the hypodermic injection of morphinæ sulphas, gr. ½ to ¼, combined with atropinæ sulphas, gr. ½ chloral, gr. x, repeated, where no heart complication exists, is often effective; drinking strong, hot, black coffee is often serviceable. Caffeinæ citrat., gr. iij hypodermically, is often valuable. Page strongly recommends sodii nitris. (R. Pulv. sodii nitritis, gr. xxiv; aquæ fʒj. M. Sig. Teaspoonful at once, repeated in half hour once or twice if necessary.) Chloroformum, æther, or amyl nitris inhalations have been recommended; also nauseant expectorants, lobelia, ipecac, scilla, or ext. grindeliæ fld. gtt. xx, repeated every two or three hours.

Dr. Pepper speaks highly of the following for the paroxysm:-

R.	Ammonii bromidi,							
	Ammonii chloridi.,							3 iss
	Tinct. lobeliæ,							f Z iij
	Spts. ætheris comp.,						٠	fžj
	Syr. acaciæ q. s., .							f Ziv.
_								O

SIG.—Dessertspoonful in water every hour or two.

M.

Another remedy that at times is successful is syrupus acidi hydriodici, mxv-xxx, every three or four hours.

Inhalations of the fumes of belladonna, stramonium, nitre-paper, chloroforum, ethyl bromidum, or the use of various pastilles or cigarettes, are of immense benefit in many cases. A twenty per cent. solution of menthol as an inhalation has been successful in some cases. Inhalations of oxygen have given excellent results in a number of cases.

Paroxysms of asthma are said to be relieved by *rectal injections* of *sulphureted hydrogen* after the manner suggested by Bergeon, of Paris.

If an attack is impending it may often be aborted by drinking freely of strong black coffee, or by full doses of the bromides.

To prevent the recurrence of the paroxysms, the general health must be cared for, and any suspected causes corrected. In all cases

a thorough examination of the nasal mucous membrane should be made and any diseased condition found removed. If chronic bronchitis be present it should be persistently treated.

Two remedies long continued frequently give good results, *potassii* iodidum in doses ranging from five to fifteen grains, and arsenicum in small doses.

Additional aids are systematic exercise short of fatigue, bathing, regulated diet, and, when possible, a change of climate.

HAY ASTHMA.

Synonyms. Hay fever; autumnal catarrh; rose fever; rose cold.

Definition. An acute, specific, catarrhal inflammation of the upper air passages, extending to the bronchial tubes, associated with spasmodic contraction of their muscular layer occurring at a particular season of the year; characterized by coryza, croupy or wheezy cough, and difficult respiration.

Causes. A predisposition, often hereditary, of the nervous system seems to be a strong etiological factor.

Persons in whom the predisposition exists have attacks excited by the inhalation of the pollen of grasses, rye, corn, wheat, or roses.

Pathological Anatomy. Hypertrophy of the inferior and middle turbinated bones; a peculiar hyperæsthesia of the mucous membrane covering the inferior and middle turbinated bones, the middle meatus, the floor of the nose and that part of the septum below the limit of the olfactory membrane are frequently associated with the disease.

Symptoms. Begins by irritation of the eyes, severe coryza, with sneezing, a clear, watery, nasal discharge, and congested Eustachian tubes, rapidly extending to the larynx and bronchial tubes, when occur a hoarse, croupy, and wheezing cough, and difficulty of breathing. The dyspnæa occurs in paroxysms, which are often as severe as those occurring during a regular asthmatic attack. There is mild depression of the nervous system in nearly all attacks.

The paroxysms remit after a few days, returning again for several days or weeks, and again remitting, the bronchial catarrh persisting for a month or more.

The constitutional symptoms are mild, unless complications occur.

Complications. The affection may extend to the finer bronchial tubes (capillary bronchitis); congestion or ædema of the lungs and pneumonia are not infrequent.

Duration. Unless a change of climate is resorted to, paroxysms of hay fever continue more or less severe for six, eight, or ten weeks of the year, each year the paroxysms growing more severe.

Prognosis. The affection never proves fatal in itself, but one or more of the following *sequelæ* may result, to wit: asthma, chronic bronchitis, or loss of the special sense of hearing or of smelling.

Treatment. No specific, unless the hypertrophy of the turbinated bones be a constant phenomenon, when their removal by the galvano-cautery would at once produce a cure.

An attack of hay asthma is often prevented by a *change of climate* during the season of the year when the attacks are most common, to wit: the *early autumn*. Any of the following locations may be selected—White Mountains, Catskills, Adirondacks, Rocky Mountains, or a sea voyage.

Attacks are sometimes aborted and always relieved by the application to the nares of tablets of cocainæ hydrochloras, gr. 1/6, or a four or six per centum solution, every few hours. On several occasions pulvis ipecacuanhæ et opii, gr. v, ter die, has aborted a suspected attack, as has the following pill:—

R.	Atropinæ sulph.,	٠			٠				gr. ½	
	Morphinæ sulph.,								gr. 3	
	Strychninæ sulph.,						٠		gr. 1	
	Quininæ muriat.,	۰	۰			9			gr. x	
	Sodii arseniat., .			0			۰		gr. 1	
M	et ft. nil no vvv								_	

SIG.—One every hour until dryness, then two or three hours apart.

Success has followed the use of *quinina*, gr. v three times a day, beginning one month before the expected paroxysm.

Bartholow "has seen several cases benefited greatly" by a solution of *quinina* applied to the nares, as suggested by Helmholtz, "but to achieve success the application must be thorough and timely."

The following applied thoroughly to the nostrils has a high repute:-

R.	Menthol,		٠	۰		۰					z i	
	Cerat. simpl.,	0		٠					۰	۰	Žij	
	Ol. amygd. dulcis,			۰							f Z iss	
	Zinci. oxidi puræ,	4	۰		٠	٠		۰	٠		3 j.	
	Acid. carbolici, .	٠		۰		٠	٠				3 ss.	M.

SIG.—Apply every few hours.

A long course of *arsenicum* in minute doses sometimes removes the susceptibility to the disease.

WHOOPING COUGH.

Synonyms. Whooping cough; pertussis.

Definition. A convulsive, paroxysmal cough, consisting of a number of forcible expirations, followed by a series of deep, loud, sonorous inspirations (the whoop), repeated several times during each paroxysm, and associated with catarrh of the bronchial tubes.

Causes. Chiefly a disease of childhood, one attack generally removing the susceptibility; contagious; the result of an unknown poison, perhaps atmospheric, affecting the nervous system.

Pathology. The changes, if any, occurring in the nervous system are unknown. It is said that "irritation of the internal branch of the superior laryngeal nerve produces relaxation of the diaphragm, spasm of the glottis, and a convulsive expiration, the series of phenomena present in a paroxysm of asthma."

Hyperamia of the mucous membrane of the nares, pharynx, larynx, and bronchial tubes, with diminished secretion, followed by an increased secretion of a transparent mucus, afterward becoming purulent, the mucous membrane pale and anæmic.

Symptoms. Divided into three stages, to wit: catarrhal, spasmodic, and terminal.

Catarrhal stage originates as an ordinary naso-laryngo-bronchial catarrh, with a loose cough. Duration one or two weeks.

Spasmodic stage: The cough becomes paroxysmal, consisting of a succession of short, rapid, expiratory efforts, the face becoming red, the eyes swollen and protruding, the body bending forward, and when these expiratory efforts have exhausted the breath, they are followed by a deep, loud, crowing inspiration—the whoop: each paroxysm being composed of three such spells, the last one followed by the expectoration of a small amount of tough, viscid mucus.

The attacks of *cough* may be so severe as to cause *vomiting*, and if the vomiting occur shortly after food has been taken, the nutrition of the patient will suffer. Profuse *epistaxis* is not infrequent. *Duration* about four weeks.

Terminal stage: The paroxysms recur at longer intervals, are of shorter duration and less intensity, the catarrhal symptoms being

more marked, the expectoration freer. Duration one or two weeks, often followed by the "cough of habit."

Complications. Congestion of the lungs, capillary bronchitis, pneumonia and emphysema, or, rarely, convulsions, hydrocephalus, or apoplexy.

Diagnosis. During the catarrhal stage whooping cough cannot be distinguished from a common cold, but on the advent of the characteristic whoop the diagnosis is determined.

Prognosis. Depends upon the age and strength of the patient, the severity of the paroxysms, and the presence or absence of complications. Ordinary cases, favorable. Moderately severe attacks during infancy are followed by cerebral symptoms, while attacks occurring in adults are followed by chest symptoms.

Treatment. No specific. A self-limited disease. Remedies will not cure the disease, but often lessen the duration of or modify the severity of the symptoms.

Prof. Da Costa prefers quininæ sulphas, in full doses, or chloral in good-sized doses, often advantageously combined with the bromides, and the use of a spray of sodii bromidum (gr. xx, and aquæ, fʒj), to which may be added extractum belladonnæ fluidum, mjj. A remedy of great utility is ammonii bromidum. Excellent results have followed the use of acetanilidum, gr. j-iij, every three or four hours, according to the age, or phenacetin, gr. j-ij, four times daily. Either of these drugs seem to act better if given with an expectorant. Terpini hydras gr. i-ij-v, is sometimes valuable.

Belladonna may be added to any of the remedies named, with advantage.

The use of *cocaine* lozenges modifies the paroxysms in some cases. Dr. Keating reports "remarkable improvement in four cases of whooping cough by the use, four or six times daily, of a spray composed of"—

B .	Ammonii bromid.,								
	Potassi bromid.,		. a:	a.		o		٠	3 j
	Tinct. belladonnæ,								f g j
	Glycerini,								fži
	Aquæ rosæ								

The diet of the patient must be regulated, the clothing to be warm but not too heavy, and the patient kept in the open air as long as possible.

EMPHYSEMA.

Synonym. Vesicular emphysema.

Definition. Dilatation of, or increase in the size and capacity of the air vesicles, characterized by enlargement or distention of the lungs, difficulty of breathing, especially on exertion, and associated sooner or later with dilatation of the heart.

Causes. The *predisposing* cause of emphysema is a hereditary nutritive derangement of the lung structure, often associated with a rigid enlargement of the thorax.

The exciting cause is the result either of a too forcible and long continued inspiration—the theory of inspiration—or the excessive mechanical distention of the vesicular walls by forced expiration—the theory of expiration. But for either of these theories to be operative the lung structure must be congenitally weak, for if violent respiratory efforts alone were the essential factor, the disease would be much more frequent.

What is known as vicarious emphysema is a distention of the air cells of the healthy portion of the lung, some other part being the seat of consolidation.

Interlobular emphysema is the presence of air in the spaces between the lobules of the lungs underneath the pulmonary pleura.

Pathological Anatomy. The situation of vesicular emphysema is, in the majority of cases, the *superior portions* of the chest, and is more marked on the *left* side than on the right.

An emphysematous lung feels remarkably soft to the touch, and upon cutting, a dull, creaking sound is barely perceptible. It is of a pale red color, the vesicular walls are thinner and slighter, the vesicles are greatly enlarged, sometimes to the size of a pea or bean, and have an irregular shape, and traversing most of these large cysts (dilated vesicles) a few delicate bands, the remains of the lacerated interalveolar septa, are visible. With the destruction of the septa many of the capillaries are destroyed, whereby the emphysematous tissue is remarkably bloodless and dry.

In consequence of the destruction of so many of the capillaries, the obstruction to the pulmonary circulation becomes so great that the pulmonary artery and right cavities of the heart are greatly distended; finally, the muscular tissue of the heart undergoes granular, followed by fatty degeneration. The distention of the veins results

in a general venous stasis, to wit: nutmeg liver, congested kidneys, and gastro-intestinal catarrh.

Symptoms. The disease is often not suspected until it is well developed. The chief symptoms of vesicular emphysema are difficulty of breathing (dyspnoa), greatly aggravated on exertion, more or less cough, the result of an attending bronchitis, and the various symptoms resulting from dilatation of the heart, particularly cyanosis without marked distress. The discomfort of the patient is often increased by paroxysms of asthma.

Inspection. The shoulders are rounded, the intercostal spaces widened, the vertical diameter elongated, with circumscribed prominences between the clavicles and nipples, often increased by the act of coughing—the peculiar "barrel-shaped" chest, characteristic of this disease.

The character of the respiratory movements is marked, there being but slight movement observed on forcible respiration, the chest having the constant appearance of a full inspiration.

Palpation. The vocal fremitus is diminished, and the cardiac impulse depressed and nearer to the sternum.

Percussion. The resonance is increased (hyper-resonant) over all the emphysematous portions, and if the whole lung be involved, extends to the seventh or eighth rib anteriorly and to the twelfth rib posteriorly. The hepatic dullness may not begin until the inferior margin of the ribs is reached; the cardiac dullness is lessened, on account of the emphysematous lung nearly covering the heart.

Auscultation. The vesicular murmur is weakened, and in pronounced cases almost absent. If bronchitis be present, the inspiratory sound may be rough or sibilant in character, but its duration is always shortened. Expiration is always prolonged, and if bronchitis be present, may be associated with more or less pronounced moist or bubbling râles.

The first sound of the heart is lessened in intensity and duration, the second sound being sharply accentuated.

Diagnosis. Bronchitis is distinguished from emphysema by the absence of dyspnæa, hyper-resonance of the chest, changes in its shape, size and movements, and the disturbance of the circulation.

Spasmodic asthma by the paroxysmal character of the affection, emphysema being a permanent malady, with attacks of asthma.

Cardiac diseases due to other causes than emphysema do not have the characteristic physical signs of that affection.

Prognosis. Vesicular emphysema is essentially a chronic disease. In itself it rarely proves fatal, but if aggravated, from any cause, or if associated with frequent or prolonged asthmatic paroxysms the cardiac changes are hastened, general dropsy supervenes, death occurring from exhaustion, or, more commonly, as the result of intercurrent attacks of pneumonia.

Treatment. It being impossible to restore the altered lung structure, the indications for treatment are to relieve the *symptoms* and to endeavor to prevent its further *progress*.

For the relief of the asthmatic paroxysms, morphinæ sulphas combined with atropinæ sulphas may be used hypodermically, or ext. quebracho fld., f3ss-j, every hour until relief, or large doses of potassii bromidum, frequently repeated, or inhalations of oxygen.

For attacks of bronchial catarrh use:-

В.	Ammonii chloridi,												
	Spts. frumenti,	٠		٠			٠			٠	٠	f 3 iv	
	Glycerini,			٠						٠	۰	fĪj	
	Syr. prun. virg., .					ad					۰	f Ziv.	M.
Stc.	-Half-tablespoonfu	1 6	VP	rv	fe	w I	101	nrs	 VP	11 .	dil	nted	

SIG.—Half-tablespoonful every few hours, well diluted

To prevent the progress of the affection, remove the bronchial catarrh, relieve the difficulty of breathing, and strengthen the cardiac action, no one combination seems comparable with the following:—

Potassii iodidi,											
Strychninæ sulph., .		٠					٠	٠		gr. 1/40	
Liq. potassii arsenit.,	۰		٠			٠	٠			mγ	
Aq. laurocerasi,	٠	۰	۰		0	0	o	0	0	fʒj.	M.
 				_							

SIG.—Four times a day, well diluted.

But of all means hitherto proposed for the relief of emphysema, nothing has approached the *inhalation of compressed air*, by means of the apparatus of Waldenberg.

For attacks of cyanosis a free venesection often saves life.

The *dropsy* arising from failure of the heart to compensate for the circulatory derangement in the lungs, may be relieved for a time by the use of *digitalis*, or, if this fails, *scilla*, combined with *hydragogue* cathartics.

HÆMOPTYSIS.

Synonyms. Bronchial hemorrhage; broncho-pulmonary hemorrhage; bronchorrhagia.

Definition. The expectoration of pure or unmixed blood, usually of a bright red color, following the act of coughing.

Causes. In the majority of cases, the result of *tubercular* deposition in the walls of the minute bronchial arteries; excessive cardiac action; bronchial congestion; excessive bodily exertion, straining, lifting or running; a symptom of *hæmophilia* ("bleeder's disease").

Pathological Anatomy. Hæmoptysis rarely causes death in itself, so that few opportunities for observing post-mortem appearances are obtained, and when they do occur, the location of the hemorrhage is seldom found.

The air passages are more or less filled with clotted blood, the mucous membrane is swollen, and of a dark-red color, rarely, pale and bloodless. The air-cells contain blood clots, or are distended with air, the bronchi being filled with clots, preventing its escape. Unless the clots are rapidly removed by expectoration or absorption, a secondary inflammation develops around about them.

Symptoms. "Spitting of blood" occurs suddenly; rarely, it is preceded by epistaxis, cardiac palpitation, and some difficulty of breathing.

It begins with a sensation of warmth under the sternum, tickling in the throat, a sweetish taste in the mouth, which, upon attempting to remove by the act of coughing, a warm, saltish, bright red, frothy liquid gushes from the mouth and nose. The quantity of blood raised varies from an ounce to a pint. The appearance of the blood depresses the individual, he becoming pale, tremulous, often fainting.

The attack may subside within half an hour to several hours, returning for several days, in the meantime the expectoration being either bloody or streaked with blood.

A slight febrile reaction, with chest pains, supervenes upon the hemorrhage, the result of the inflammation at the site of the bleeding, which soon subsides, except where blood clots develop a secondary pneumonia, which may undergo the cheesy metamorphosis.

Auscultation. Coarse, bubbling râles are heard in circumscribed portions of the chest.

Diagnosis. From *epistaxis*, or hemorrhage from the posterior nares, it is distinguished by the absence of air bubbles and an inspection of the fauces and the nasal cavities.

Hæmatemesis, or hemorrhage from the stomach, differs from hæmoptysis in the blood being vomited instead of expectorated, of a dark color, clotted, mixed with the acid contents of the stomach, followed with black, tar-like stools, and the absence of râles in the chest.

Exceptions to the above occur when the blood from the lungs is first swallowed and afterwards raised by vomiting, or when the hemorrhage in the stomach is caused by the erosion of a large artery, the result of ulcer of the stomach; in these cases, however, the raising of blood is preceded by epigastric pain and the blood is not frothy.

Prognosis. Hæmoptysis in itself rarely terminates fatally, although causing much depression; the patient rapidly recovers, unless secondary pneumonia results. In nine cases out of ten it is the diagnostic sign of phthisis.

Treatment. Perfect rest in bed, the head and shoulders elevated, and perfect quiet, the diet to be bland, the drinks cool, the patient slowly swallowing small particles of ice. An ice bag over the chest, if it does not cause chilliness, is valuable. Common salt, slowly dissolved in the mouth, is a popular remedy, and if of no real benefit, serves to occupy the attention of the patient and friends until medical advice is obtained.

The hypodermic injection of atropinæ sulphas, gr. $\frac{1}{60}$, will usually at once control a hemorrhage. It may be repeated pro re nata.

The hypodermic injection of ergotin, gr. x-xxx, or the internal administration of extractum ergotæ fluidum, 3ss-j are valuable, or:—

Acid.	gallic., sulph. dil cinnamo	., .				٠		٠	mχ	М.
_									•	

Sig.—Repeated every fifteen or twenty minutes.

Or tinctura matico, f3j, or extractum hamamelis fld., mxx-f3j, alumen, gr. xx, or acidum gallicum, gr. v-x, frequently repeated.

If the hemorrhage causes great nervous excitement, or depression, *morphina*, either hypodermically or internally, to quiet the patient, is indicated.

Inhalations, by means of the steam atomizer, of either Monsel's

solution or tinctura ferri chloridum, are recommended when the above means fail.

Prof. Da Costa recommends, for frequent small hemorrhages, continuing day after day, *cupri sulphas*, gr. $(\sqrt{2}\pi)$, ext. opii, $(\operatorname{gr.} \frac{1}{12})$, p. r. n.

DISEASES OF THE LUNGS.

CONGESTION OF THE LUNGS.

Synonyms. Pulmonary engorgement; hypostatic congestion.

Definition. An increase in, or abnormal fullness of, the capillaries of the air cells; *active* congestion when the result of an accelerated circulation; *passive* congestion when caused by an impeded outflow from the capillaries.

Causes. Active. Increased cardiac action; over-exertion; alcoholic excesses; mental excitement; inhalation of cold or hot air.

Passive. Obstruction to the return circulation. Dilated heart; valvular diseases; low fevers (hypostatic congestion); Bright's diseases.

Pathology. The hyperæmic lung has a bloated, dark-red appearance; its vessels are distended to the uttermost, the tissues succulent and relaxed, blood flowing freely over the cut surface; a bloody, frothy liquid is present in the bronchi, and the alveolar walls are so much swollen that the condensed lung shows scarcely any indication of its cellular structure, resembling the tissue of the spleen (splenification).

Symptoms. Active. Rapidly developing thoracic distress and difficulty of breathing, flushed face, strong, full pulse, throbbing carotids, cardiac palpitation and congested eyes, with a short, dry cough, followed by scanty, frothy expectoration, slightly streaked with blood.

Passive. Developed slowly, with difficulty of breathing, blueness of the surface, almost continuous hacking cough, followed by scanty, blood-streaked expectoration.

Percussion. The resonance of the lungs slightly diminished, the quality of the sound being somewhat tympanitic.

Auscultation. The vesicular murmur is diminished and accompanied with *sub-crepitant râles*.

Duration. Active. Usually from three to five days, terminating either by resolution, hemorrhage, or, rarely, pneumonia. The onset may be so severe and overwhelming that death rapidly supervenes.

Passive. Developed slowly, and subject to great variations, depending upon the cause.

Diagnosis. Active congestion of the lungs cannot be distinguished from the stage of engorgement of a true pneumonia.

Prognosis. An acute congestion of the lungs may prove fatal within a few hours, but under prompt treatment it generally terminates favorably.

The passive form is controlled entirely by the cause.

Treatment. Active. In the strong and vigorous wet cups to the chest, or, if the symptoms are pronounced, a general venesection. Internally, tinctura aconiti, gtt. j-ij every half hour or hour, as indicated, with free catharsis with saline purgatives.

Passive. Dry or wet cups over the chest, hydragogue cathartics, and the internal administration of digitalis: if much depression of the vital powers, stimulants such as spiritus vini gallici and spiritus ammoniæ aromaticus, are indicated.

ŒDEMA OF THE LUNGS.

Synonym. Pulmonary ædema.

Definition. An exudation of serum into the pulmonary interstitial tissue and the alveoli of the lungs; characterized by dyspnœa, cough, and a frothy, blood-streaked expectoration.

Causes. Pulmonary ædema is the result of stasis, occurring when the outflow of venous blood in the lung meets an obstacle that cannot be overcome by the right ventricle, as in cardiac diseases, in which the left ventricle fails. Bright's disease; alcoholic excesses, causing cardiac depression. Sequelæ to other lung inflammations.

Pathological Anatomy. The lung tissue is swollen, and does not collapse when the chest is open. The elasticity of the tissue has disappeared, and it pits upon pressure.

If following congestion of the lungs, the color is red; if a symptom of a general dropsy, its color is pale.

On cutting into the cedematous spots an enormous quantity of

albuminous fluid, sometimes clear, at other times of a red color, mixed more or less with blood, flows over the cut surface. The liquid is filled with bubbles, is frothy, from being copiously mixed with air, providing the air cells have not been entirely filled with scrum, thereby excluding the air.

Symptoms. The pre-eminent symptom is dyspnwa, the breathing being hurried, labored and rattling, all the accessory muscles of respiration being called into action. The sense of oppression and anxiety is extreme. There is also a constant, harassing, short cough, and the expectoration is a blood-streaked, frothy mucus. The action of the heart may be tumultuous or feeble. The face is at first flushed, but as the left ventricle fails or if the effusion into the air cells be sufficient to prevent the entrance of air, symptoms of cyanosis rapidly supervene, the pulse becoming feeble, the surface cold, the breathing shallow and hurried, the cough suppressed, stupor replacing the restlessness, soon deepening into coma,

Percussion. If no other lung disease, the percussion note is but slightly, if at all, impaired.

Auscultation. The vesicular murmur is lost by the diffused subcrepitant and bubbling râles.

Diagnosis. Acute Pneumonia in the earlier stages is the only condition likely to be confounded with ædema of the lungs, but as the two diseases progress, the picture of puimonary ædema is so characteristic that it cannot be mistaken.

Prognosis. Grave, and particularly if occurring in pneumonia, cardiac, or Bright's disease. In the majority of instances it is a terminal symptom coming on in all forms of acute and chronic diseases.

Treatment. As a rule, remedies are useless. The indication is to hold up the left heart, and this is best done with hypodermic injections of strychninæ sulphas, $gr. <math>\frac{1}{24}$, repeated every half hour, caffeinæ citras, gr. iij-v, sparteinæ sulphas, gr. j-ij, every hour or two, or digitalinum, $gr. <math>\frac{1}{60}-\frac{1}{30}$, repeated every hour or two. One or more of these drugs may be advantageously combined. Atropinæ sulphas, $gr. \frac{1}{60}-\frac{1}{100}$, and ergota in some form are valuable remedies. Occasionally relief follows a free venesection or the application of wet cups. Alcoholic stimulants are often invaluble.

The above means may be aided by counter-irritation to the chest, hot mustard foot-baths, active saline purgatives, and diuretics.

CROUPOUS PNEUMONIA.

Synonyms. Lobar pneumonia; pneumonitis; fibrinous pneumonia; pleuro-pneumonia; lung fever; winter fever.

Definition. An acute, infectious, croupous inflammation, involving the vesicular structure of the lungs, rendering the alveoli impervious to air; characterized by a severe chill, headache, fever, thoracic pain, dyspnæa, cough, rusty sputum, and great prostration.

Causes. Croupous pneumonia is an infective disease caused by the *diplococcus pneumoniæ* of Frænkel, "which has its seat of election in, and produces its chief effects on the lung."

All ages liable. Males more frequently affected than females. One attack predisposes to another. Debilitating causes render individuals more susceptible. Alcoholism is one of the most frequent predisposing factors. It is most frequent in winter, at times occurring *epidemically*, the result of atmospheric conditions; exposure to draughts and cold. Gout, rheumatism, diabetes, and Bright's disease.

Pathological Anatomy. The most frequent seat of croupous pneumonia is the lower *right* lobe; the next most frequent seat is the lower *left* lobe; the next, the upper right lobe, although in children and the aged this lobe is affected equally as often as the right lower lobe.

The changes are, I. *Hyperamia* (engorgement); II. *Exudation* (red hepatization); III. *Resolution* (gray hepatization); or it may undergo purulent transformation or the development of abscesses (yellow hepatization).

- I. Stage of hyperæmia or engorgement consists in the vessels of the alveoli being distended to their utmost, encroaching upon the cavity of the air vesicle; the lung has a reddish-brown color, is heavier, sinking somewhat lower in water than a normal lung, and having a slight exudation upon the vesicular surface. The same changes are perceived in the adjacent bronchioles.
- II. Stage of exudation, consists in the exudation of a viscid, fibrinous fluid, admixed with white and red corpuscles and blood, which rapidly coagulate, firmly enclosing the corpuscles and completely filling the alveoli. When the exudation and coagulation are completed, the lung is red, sinks at once when placed in water, and its elasticity is destroyed. When cut into, the color, density and granular appearance so closely resemble the cut surface of a section of the liver, that Lænnec termed it red hepatization.

A thin section shows under the microscope, as a rule, the lancet-shaped diplococcus of Frænkel, as well as staphylococci and streptococci.

III. Resolution, or gray hepatization, follows the above condition in the majority of cases, the coagulated albuminous exudation undergoing liquefaction and absorption, the cellular element undergoing a fatty degeneration, the greater part being absorbed, the remainder expelled during acts of expectoration, the alveoli returning to their normal condition, both as to capacity, function and elasticity.

If resolution be retarded and portions of the coagulated exudation undergo *purulent transformation*, changing from a yellowish to a greenish-yellow color (yellow hepatization), pus cells are rapidly formed, the part becoming a granular, fatty mass. The portions of the lung not undergoing this purulent transformation retain the reddish color with intermixed yellowish patches, the lung structure proper remaining intact. The purulent contents may be ejected in part, the remainder undergoing fatty degeneration and finally absorption.

Abscess of the lung may result from the lung structure becoming involved in the purulent disintegration. Abscesses may be solitary or in great numbers, which by disintegration of intervening structure form one or more large abcesses; these abscesses either terminate fatally, or open into the pleural cavity, causing empyema and exhaustion, or open into the bronchi and are expectorated, or an interstitial pneumonia is developed and the abscess encapsulated in a firm cicatricial tissue.

Gangrene of the lungs may result from blocking up of the bronchial or pulmonary arteries by coagula, during any stage of the disease.

The uninflamed portions of the lungs are hyperæmic and their functional activity is increased.

Death sometimes results from a *general wdema* of the unaffected lung, such cases being often erroneously termed "double pneumonia."

If inflammation of the *pleura* be associated with a pneumonia, the so-called *pleuro-pneumonia*, the changes in the pulmonary pleura are characteristic. "An uneven, thin, downy-looking layer of plastic exudation covers its surface. This plastic layer may conceal the liver-brown color of the pneumonic lung. As the third stage is reached, the opposing surfaces of the pleura may become agglutinated. The pleuritic changes follow very closely those which occur within

the lung. The cells in the pleuritic exudation are mainly pus. The pleuritic membrane is opaque, congested and ecchymotic. It may become so thick as to give a dull note on percussion, after resolution is reached."

Duration of Stages: stage of congestion, from one to three days; stage of exudation, from three to seven days; stage of resolution, from one to three weeks.

In severe cases or in the very young, the aged or the depressed, the stage of red hepatization may be fully developed within forty-eight hours.

Symptoms. Begins with a severe and usually protracted chill (in children often convulsions, adults vomiting), followed by a rapid rise of temperature, 103-104° F., a strong, full, but rapid pulse, soon showing evidences of embarrassed cardiac action from obstructed respiratory circulation, either a dull or sharp pain near the nipple, aggravated by pressure, breathing or coughing, shortness of breath, the inspiration short and superficial, the expiration accompanied with a moan or grunt, the number of respirations increasing to 40, 50 or more per minute, causing interrupted speech, the ratio between pulse and respiration may be I to 2 or more; cough, first short, ringing and harsh, soon followed by a scanty, frothy, mucus, soon becoming semitransparent, viscid and tenacious, about the second day changing to the familiar rusty sputum, becoming more copious and of a yellow color as the disease advances; rarely cases occur with bloody or blood-streaked sputum during the continuance of the fever. There are present headache, sleeplessness, rarely delirium, save in drunkards, epistaxis, flushed countenance, and especially over the malar bones is a well-defined mahogany blush; gastric disturbances and scanty, high-colored urine, with diminished chlorides, and often albuminuria.

From the very onset of the disease the prostration is of the most serious character.

The above symptoms continue more or less marked until either the fifth, seventh, ninth, or eleventh day, when a crisis occurs, and within twenty-four hours convalescence is established, recovery rapidly following.

Typhoid pneumonia is a term applied to those cases which are accompanied by signs of extreme prostration, delirium, tremor, very high temperature and profuse and prolonged exudation. They may also terminate by a crisis.

Bilious pneumonia occurs in cases accompanied by congestion of the liver, the result of venous stasis from pulmonary obstruction or from an accompanying acute catarrhal jaundice. In malarial districts pneumonia and malaria are often associated, when jaundice more or less pronounced occurs. Such cases are termed malarial or intermittent pneumonia.

Alcoholic, or pneumonia of the intemperate, has one very characteristic symptom, to wit, *early delirium*. In pneumonia generally the mind is clear when all the conditions are unfavorable.

Pneumonia of the *intemperate* may begin with symptoms closely resembling an attack of *delirium tremens*, cough, expectoration, and pain being very slight, or even absent.

If *purulent infiltration* follow the stage of red hepatization, instead of the crisis, symptoms of exhaustion occur, with profuse purulent expectoration, high temperature, severe sweats, the tongue brown and dry, sordes collecting on the teeth, low delirium, feeble pulse, rapid, rattling breathing, the recovery slow and convalescence tedious.

Pneumonia in the aged or the insane may be latent, coming on without chill or pain and with only a slight fever; the cough and expectoration are slight, physical signs ill-defined and changeable, and the constitutional symptoms out of all proportion to the amount of lung involved.

Inspection. First stage, deficient movement of the affected side, due to the pain.

Second Stage, the healthy side rises normally, the affected side lagging behind. If both lower lobes are impervious to air, the diaphragm cannot descend and the epigastrium does not project during inspiration, the breathing being conducted by the upper part of the chest (superior costal respiration).

Palpation. First stage, the vocal fremitus more distinct than normal.

Second stage, the vocal fremitus is markedly exaggerated except in those rare instances of occlusion of the bronchi by secretion.

The cardiac impulse is felt in the normal position.

Percussion. First stage, the percussion note is slightly impaired, indeed, at times having a hollow or tympanitic quality.

Second stage, dullness over the affected parts, with an increased sense of resistance.

Auscultation. First stage, over affected part, feeble vesicular

murmur, associated with the true vesicular or crepitant (crackling) râle, most distinct during inspiration.

Second stage, harsh, high-pitched bronchial respiration, at times resembling a to and fro metallic sound, except in those rare instances in which the bronchi are more or less filled with secretion.

Bronchophony, or distinctly transmitted voice, at times pectoriloguy. or distinct transmission of articulated sounds, is present.

Third stage, breathing changing from bronchial to vesiculo bronchial, the crepitant (crepitatio redux) râle returning, and if resolution proceed, the breath sounds are associated with large and small moist and bubbling râles.

"The morbid phenomena, physical signs and symptoms of the malady correspond usually in this matter."—(DA COSTA).

- and beginning exuda-
- cussion dullness.
- I. Stage of engorgement Crepitant râle; slight per- Cough; beginning dyspnœa and rapidly developed fever heat.
- of lung-tissue (redhepatization).
- II. Stage of solidification Percussion dullness; bronchial respiration; bronchophony.
 - Rusty-colored sputum: dyspnœa; cough; high fever with marked evening exacerbations and morning remissions.

- hepatization).
- III. Stage of softening (gray The same physical signs as in the second stage unless large abscesses have formed.
- Chills; prostration, etc.; purulent or brownish sputum; generally high temperature.

Terminations. Asthenic cases recover within two weeks. When purulent infiltration supervenes, the disease pursues a tedious course of several weeks' duration, with a low exhaustive fever.

If death occur during the first or second stages it is usually the result of a collateral ædema of the uninflamed lung, or cardiac failure and impaired nerve force.

If abscesses occur, there are exhausting sweats, frequent cough, with a large amount of yellowish-gray, at times blood-streaked, expectoration.

Gangrene of the lungs is a rare termination; it is associated with symptoms of collapse, the expectoration of a blackish, fetid sputum, and the physical signs of a pulmonary cavity.

Diagnosis. Edema of the lungs may be confounded with the first stage of pneumonia, but the subsequent history, its presence on

both sides, and the waterish expectoration and absence of chill and pain and the physical signs of pneumonia soon determine the diagnosis.

Pleurisy is oftener confounded with pneumonia than any other disease, the points of distinction between which will be pointed out when discussing that affection.

Complications. Acute pleuritis is a frequent complication of croupous pneumonia, occurring as often as from ten to twenty-five per cent. of cases. The more acute localized pain, the greater embarrassment of respiration, and the usual physical signs of effusion are the evidences of a pleuro-pneumonia.

Capillary bronchitis is a rare but dangerous complication. Pericarditis, rheumatism and gout are rare complications.

Prognosis. Depends upon the extent of the inflammation, the dangerous features of croupous pneumonia being cardiac failure, the result of a myocarditis or of embarrassed respiratory circulation, and the rapid tissue waste associated with extreme fever, 105°, resulting in impaired nerve force; double pneumonia has a very grave prognosis, but it is not nearly so frequent as was at one time supposed. The coexistence of pleuritis adds to the gravity of the prognosis, although not as fatal as generally supposed. Pneumonia of drunkards almost invariably terminates fatally. Typhoid pneumonia, pneumonia of the aged and in the insane, the so-called bilious pneumonia, purulent infil-

tration, abscesses of the lungs and gangrene, all give a grave prognosis.

Treatment. If pneumonia be regarded as a constitutional malady with a local lesion, then the consolidated lung no more calls for treatment than does the intestinal ulcer of typhoid fever, but the general condition of the patient is to govern in the management of the case and not the local changes going on in the thorax. A simple pneumonia attacking persons previously in good health requires no more active treatment than any of the so-called self-limited diseases, provided only that the extent of the disease be moderate, and there be no complication.

The much-discussed question of venesection is now a settled problem in the affection; if we bleed it is "not because of pneumonia, but in spite of pneumonia." Called to a case in the first stage of the disease, or early in the second stage, who has been vigorous and otherwise healthy, with a high temperature, 105° or more, with frequent pulse, one hundred and twenty beats or more, or a slow, full pulse showing cardiac oppression, flushed surface and marked dyspnœa, a copious bleeding is indicated, and the same may be said when symptoms of collateral œdema threaten; this is bleeding for symptoms and not for the disease per se.

There is no remedy which can in any way exert a favorable influence upon the pneumonic process. Many cases recover without any, and many cases in spite of treatment.

At the onset if venesection is not indicated, relief of the pain may follow the use of dry cups. If the tongue be coated and the gastro-intestinal canal deranged, a calomel purge is indicated. (R. Hydrargyri chloridi mitis, gr. ij, sodii bicarb., gr. iv, pulv. ipecac, gr. j. M. et ft. chart. No. iv. Sig.—One every two hours, followed in four hours after last powder by mild saline.)

Action on the skin and kidneys by refrigerant mixtures, or small doses of Dover's powder and potassii nitras is valuable. The administration of such arterial sedatives as aconitum, veratrum viride and antimony is questionable. An exception may be made in the case of pneumonia of children, where the use of small, frequently repeated doses of *tinctura aconiti* in the early stage is useful.

Poultices are of slight value, but the use of home-made mustard plasters, weakened with flour, is useful in all stages. If the heart be weak from the onset, either of the following are valuable: digitalis, caffeina, spartein, or strychnina. Quinina sulphas, gr. ij-v, every three or four hours is always of use.

Second Stage. It is at this period of a severe attack of acute pneumonia that two prominent indications for treatment arise,—heart-insufficiency and high temperature.

To sustain the heart is one of the most important indications in the treatment of an acute pneumonia, for experience shows that cardiac failure is responsible for a large number of deaths in this affection. Strychninæ sulphas, gr. ½4-3k, repeated every few hours by mouth or the hypodermic method, or caffeinæ citras. gr. ij-v, every four hours, or tinctura strophanthus, gtt. v-x, every three hours, are valuable cardiac tonics in pneumonia. Alcoholic stimulants judiciously employed are most efficient means for preventing or overcoming the cardiac failure. The amount can only be determined by a careful study of each case, as a few ounces in the twenty-four hours may answer in one case, while another case may require eight or ten ounces. It is well to

begin with small doses, increasing or decreasing as its effects are good or bad. The indicator of the heart's condition is the pulse. In the aged, the feeble, or in those accustomed to the use of alcohol, stimulation is indicated from the onset. Other indications would be a frequent, feeble, irregular or intermitting pulse; a dicrotic pulse; delirium, muscular tremor and subsultus; immediately following crisis, and the period of collapse.

To reduce the temperature is also an important indication. If the fever is under 103° F., cool sponging with alcohol and water, or water alone, is usually sufficient. If the temperature is above 103° F., antifebrin, gr. v, should be used every three hours until a reduction occurs. Strychnina or caffeina may be added to each dose. Phenacetin or acetanilidum are also valuable, and considered less depressing.

The use of the cold pack or of cold baths for reducing the temperature in acute pneumonia has not met with the approval of practical clinicians.

Dr. Mays strongly advocates the use of *ice bags* to the chest in pneumonia. He says: "Very often it is found that the application of the ice to an affected spot is immediately followed by a marked lowering of the temperature, and improvement in the physical signs in the part."

The diet must be of the most nutritious but easily digestible character, and given at periods of every three hours. Strong black coffee throughout the disease is valuable.

Third Stage. The treatment is a continuation of that of the second stage, gradually reducing the antipyretics as the fever declines, and adding one of the preparations of ferrum.

Convalescence. Nutritious diet, quininæ sulphas in tonic doses, ferrum, together with a good blood-making wine or a good preparation of malt. If the consolidation shows a disposition to linger, blisters may be used.

Many cases are favorably influenced by an expectorant from the onset of the disease. The following is valuable: (R. Ammonii chloridi, gr. v-x; strychninæ sulph., gr. $\frac{1}{2^4}$; aquæ chloroform., f \mathfrak{Z} j-ij. M. Sig.—Every three hours).

The various symptoms other than those particularly mentioned are to be met, as they arise, by their proper remedies.

For typhoid pneumonia, purulent infiltration, abscess of the lungs,

or pneumonia in drunkards, the weak or the aged, quinina, ferrum, nutritious diet and bold stimulation, and the free use of ammonii carbonas or spiritus ammoniæ aromaticus, are the indications.

The so-called *antiseptic* treatment of acute pneumonia is still under trial, and no definite opinion can be expressed concerning it.

CATARRHAL PNEUMONIA.

Synonyms. Broncho-pneumonia; lobular pneumonia; capillary bronchitis (?).

Definition. An acute catarrhal inflammation of the bronchioles and alveoli of the lungs, characterized by fever, cough, dyspnæa, copious expectoration and great depression.

Causes. From an extension of a bronchial catarrh downward; following the eruptive fevers, especially measles; complicating whooping cough. Persons of the rickety or scrofulous diathesis, in whom there is a greater irritability of the epithelial elements, are particularly predisposed to this form of pneumonia on slight exposure; emphysema; diseases of the heart; most frequently seen in childhood and old age.

Bacteriological investigations seem to indicate that secondary broncho-pneumonia is due to more than one germ.

Pathological Anatomy. Hyperamia of the mucous membrane of the bronchi, extending to the connective tissue of the bronchioles and accompanying arterioles and to the alveoli, with swelling and succulence of these tissues, accompanied by an abnormal secretion and an immense production of young cells from the proliferation of the bronchial and alveolar epithelium, admixed with a yellowish, creamy, mucoid material, which blocks up the bronchioles and air cells.

The affected parts first have a reddish-gray, soon changing to a yellowish-gray color, due to the rapid metamorphosis of the newly developed cells. If the fatty change be completed, absorption takes place, and the consolidation is removed; if it remain incomplete the cells atrophy, the little mass becoming caseous, and the disease passes into a chronic state.

The bronchial tubes also participate in the disease, the walls become thickened, from a hyperplasia of the connective tissue (*peribronchitis*), and their calibre is often dilated.

Symptoms. Catarrhal pneumonia begins as a catarrhal bronchitis. It may be either *acute*, *sub-acute* or *chronic* in its course.

Acute variety: Its onset is announced by a gradual rise of temperature to 102°-103° F., the febrile phenomena assuming a typical remittent character, with rapid, laborious and shallow breathing, as shown by the widely dilated nares and violent action of all the accessory muscles, while the insufficient distention of the lungs is shown by the great recession of the lower part of the chest walls and sinking in of the intercostal spaces. The inspiration is short and imperfect, the expiration noisy and prolonged; the pulse is frequent, 100-120 or more, and somewhat compressible; the cough, which, during the bronchitis, was loose, now becomes short, hacking, dry and painful, soon followed by more or less copious muco-purulent expectoration; the appetite is impaired, bowels somewhat loose, urine scanty, high-colored, and the surface frequently covered with a more or less profuse perspiration.

The *sub-acute* and *chronic* varieties have the same general symptoms, but the duration is longer and the exhaustion greater.

The progress of catarrhal pneumonia is sometimes, although not often, a very acute one. The disease may prove fatal in a few days, especially if it attack feeble children; in such the countenance becomes pale and livid, the lips bluish, the eyes dull, and a restlessness giving place to apathy, and a continually augmented somnolence.

Resolution, when it occurs, is by *lysis*, several weeks elapsing before complete recovery.

Percussion. *Dullness*, scattered in patches, over both lungs, the intervening healthy lung often giving a more or less *hollow* or *tympanitic* note.

Auscultation. Vesiculo-bronchial breathing, changing to moist bronchial breathing, associated with small bubbling (sub-crepitant) râles. As the disease progresses toward resolution, the râles become larger (large bubbling) and more copious. If pneumonic phthisis result, physical signs indicative of that condition are soon evident.

Sequelæ. Attacks of catarrhal pneumonia complicated with atelectasis, or collapse of the lobules, when recovery occurs, are followed by emphysema of the lungs.

If the catarrhal products which fill the alveoli and bronchioles and intervening connective tissue do not rapidly undergo complete fatty

metamorphosis and consequent absorption, pneumonic phthisis results.

Diagnosis. Ordinary bronchial catarrh differs from catarrhal pneumonia by the absence of dyspnæa, fever, and dullness on percussion, and the presence of the large bubbling râles, and also by the subsequent history of the two affections.

Croupous pneumonia is a unilateral disease; catarrhal pneumonia is bilateral and diffused over both lungs; the former a self-limited disease, the latter having no fixed duration.

Acute tuberculosis at its onset is characterized by the presence of a capillary bronchitis, a differentiation being possible only by a study of the clinical history and course of the two maladies and the presence or absence of the tubercular bacilli.

Ædema of the lungs is a bilateral disease associated with a short, dry cough, and dyspnæa, but lacks the previous catarrhal history and high temperature of catarrhal pneumonia.

Prognosis. Fully one-half of the cases of true catarrhal pneumonia terminate fatally. The prognosis must be guarded in scrofulous or rachitic subjects, or those enfeebled by other diseases, for unless prompt resolution can be effected, it will terminate fatally early, or develop pneumonic phthisis. Have seen cases continuing up and down for eight and ten months, and finally make a good recovery.

Treatment. Confinement to bed is paramount, although the position of the patient is to be frequently changed. The *diet* must be of the most nutritious character, administered at frequent intervals; milk, eggs, chicken, beef, mutton and oyster broths are the most suitable articles. The steady use of *brandy* or *whiskey* throughout the attack is of importance, regulating the amount by the age of the patient and the severity of the attack.

Locally a weak mustard plaster followed with a cotton batting jacket is valuable. Poultices of little use. The febrile symptoms and early cough are often modified by the following mixture: (R. Potassii citratis, 3vj; spts. ætheris nitrosi, f3iv; tinct. opii camphorat., f3iv; liquor potassii citratis, ad f3vj. M. Sig. Dessertspoonful every three hours). Early in attack, in children with high temperature, tinctura aconiti, in small frequently repeated doses. If the fever persists a combination of phenacetin or antifebrin, camphor, and digitalis is useful. The ice bags or poultice are as strongly urged for broncho-

pneumonia as for croupous pneumonia, and in sthenic cases should be given a trial.

For the catarrhal process, the air of the apartment should be maintained at an even temperature and moistened by disengaging the vapor of water in it. The following combination is of great utility in nearly all cases, regulating the dose in accordance with the age of the patient:—

R.	Ammonii carbonat.,		٠							gr. v
	Ammonii iodidi, .									gr. v-x
	Mucil. acaciæ,									q. s.
	Syr. glycyrrh.,			٠		٠				f ʒ j-ij
	Syr. prun. virg.,	 			٠	q.	. S.	a	d	f 3 ij-iv
STO	Every three hours									

A much pleasanter way of administering the *ammonia* salts is in capsules, each containing about two and one half grains of each salt with an aromatic oil. *Terpinum hydras* acts remarkably well in many lingering cases.

For convalescence, nutritious food, ferri iodidum, quininæ sulphas, and oleum morrhuæ.

Locally: repeated application of mustard poultices or turpentine stupes followed by cotton jacket. If the inflammatory processes tend to become chronic, scattering blisters should be used.

PULMONARY TUBERCULOSIS.

Synonyms. Phthisis pulmonalis; phthisis; consumption; pneumonic phthisis; tubercular phthisis.

Definition. An infective disease, caused by the *bacillus tubercu-losis*, the lesions of which are characterized by nodular bodies called tubercles or diffused infiltrations of tuberculous tissue which undergo caseation or sclerosis and may finally ulcerate, or in some situations calcify. (Osler.)

Clinical Varieties. I. Acute miliary tuberculosis; II. Pneumonic phthisis; III. Tubercular phthisis; IV. Fibroid phthisis.

Cause. It is now generally accepted that all varieties of pulmonary consumption are due to the active presence of the *bacillus tuberculosis*, discovered by Koch in 1881. The lung tissues must be in a receptive state as the bacilli may be present in the respiratory tract without the development of the disease.

Any condition that lowers the tone of the general system, renders the tissues susceptible to the changes produced by the tubercle bacilli. These will be enumerated in speaking of the clinical varieties of the disease.

ACUTE MILIARY TUBERCULOSIS.

Synonyms. Acute phthisis; galloping consumption.

Definition. An acute infective febrile affection, due to the rapid eruption in various parts of the body, but especially in the lungs, of miliary tubercles; characterized by high fever, rapid pulse, hurried respiration, pains in chest, cough, profuse expectoration and rapid prostration.

Causes. In the majority of cases it is the result of an auto-infection, arising from either an active or latent tuberculous focus. Cases develop in which no cause can be assigned. Often follows measles, whooping-cough, variola, and influenza.

Most common between puberty and middle life.

"That the gray granulation is deposited throughout the body under the influence of certain conditions of irritation, it is necessary that a peculiar vulnerability of the constitution exist, in other words, that it be of the scrofulous type."

Clinical Forms. General or typhoid, pulmonary and cerebral. The cerebral will be described in the section on nervous diseases.

Pathological Anatomy. Pulmonary form. "The gray granulation or miliary tubercle consists of a fine reticulation of fibres, with a mass of epithelioid cells and granules, and often having a giant cell for its centre."

The deposit is generally over both lungs and the bronchial tubes, and is followed by hyperæmia, increase of secretion, having a viscid and adhesive character, and the destruction of all the tissue with which it comes in contact.

Deposits also take place in the brain, pleuræ, intestines, peritoneum and kidneys.

General or Typhoid.—Symptoms. Gradual progressive weakness, with loss of appetite, dry, clean tongue, costive bowels, flushed cheeks, fever, irregular in type, and rapid, feeble pulse. Rarely the temperature reaches 103° F., to 104° F., associated with a mild delirium. The respirations are increased with slight or no cough, and

little or no expectoration. As the symptoms continue the prostration increases, cyanosis develops, the patient growing stupid, gradually deepening into coma and death.

Diagnosis. There are none or so slight local conditions, the symptoms pointing to an acute general infection, that the disease is apt to be mistaken for typhoid fever. The points of difference are the absence of the typical typhoid temperature record, the characteristic eruption, and the diarrhea.

Prognosis. Recovery is the rarest termination.

Treatment. Expectant and symptomatic.

Pulmonary Form.—Symptoms. The onset is usually sudden, with a chill or chilliness, followed by fever, 102°-104° F., rapid, dicrotic pulse, 120-140, cough, with scanty, glairy sputum, increased respiration, 30-50 per minute, pain in the chest, hot skin, dry tongue, deranged digestion and great prostration, the severity of the symptoms rapidly increasing, with evidences of cyanosis, the sputum becoming more abundant and often rusty in color, with more or less frequent attacks of hæmoptysis, soon followed by headache, vertigo, sleeplessness, often delirium, coma and death.

If deposits have occurred in the meninges or the intestines, symptoms of these affections are superadded.

Percussion. The percussion resonance is normal until considerable deposits have occurred, when it is either slightly *impaired* or even slightly *tympanitic*. With the development of cavities the *amphoric* percussion note is present.

Auscultation. Vesiculo-bronchial breathing, associated with large and small, moist or bubbling râles, soon followed by bronchial and broncho-cavernous breathing, with large and small, moist and circumscribed gurgling râles.

Duration. Acute phthisis usually terminates fatally in from four to twelve weeks. Rarely of several months' duration.

Diagnosis. Commonly mistaken for typhoid fever with lung complications, an error that is readily made unless a close study of the history, symptoms, physical signs, and sputum be made.

Treatment. There are no means of retarding the progress of this malady. Loomis says: "Morphia in small doses—one-twentieth of a grain hypodermically every six or eight hours—has, in my hands, been more satisfactory in staying the progress of the disease, prolonging life, and keeping the patient comfortable, than any other plan."

Dr. McCall Anderson claims that subcutaneous injections of atropina check the exhausting sweats; and that quinina, digitalis and opium reduce the temperature, and if they fail, ice cloths to the abdomen will accomplish the desired result.

The various symptoms should be met as they occur, the patient at the same time being supplied with large quantities of *stimulants*.

PNEUMONIC PHTHISIS.

Synonyms. Chronic catarrhal pneumonia; catarrhal phthisis; caseous pneumonia; caseous phthisis.

Definition. A form of pulmonary consumption characterized by the destruction of the pulmonary tissue resulting from the action of the bacilli, causing the *cascation* or cheesy degeneration of inflammatory products in the lungs, and the subsequent softening and destruction of the caseous matter, with greater or less destruction of the pulmonary tissue; characterized by hectic fever, cough, shortness of breath, purulent expectoration, and more or less rapid prostration.

Causes. The *predisposing* factor in the etiology of pneumonic phthisis is a strumous or scrofulous diathesis, or a condition of lowered health, the result of various unfavorable hygienic influences.

The exciting causes are: the irritation produced by the presence of the bacillus tuberculosis and a catarrhal pneumonia in any portion of the lung, but especially at the apex; inflammation occurring about a blood clot; inhalation of irritant particles occurring in certain occupations, to wit: weavers, grinders, miners, hatters, millers, cigar makers, and the like. Many cases of pneumonic phthisis can be traced to an attack of influenza a year or so before.

Pathological Anatomy. When a pneumonia terminates in resolution the inflammatory products are absorbed by first undergoing a fatty metamorphosis. If the fatty metamorphosis be incomplete, the cells are atrophied and undergo the caseous degeneration, which consists in the absorption of the watery parts, the fatty degeneration of the cellular elements, and the granular disintegration of the fibrinous material, so that ultimately a soft, solid mass is produced, yellowish in color, having the appearance of cheese.

The destructive changes are thus described by Niemeyer: "Cells, the products of inflammation, accumulate in the alveoli and minute bronchi crowd upon each other, becoming densely packed, and thus

by their mutual pressure they bring about their own decay, as well as that of the lung textures, by interfering with their nutrition, the alveolar walls being also themselves damaged by the inflammatory process."

The position of the catarrhal pneumonia resulting in the above changes is usually at the apex, but it may occur at any portion of the lungs, or a whole lung becomes infiltrated, and undergoes the cheesy degeneration (phthisis florida).

Symptoms. Pneumonic phthisis occurs in three forms, the chronic, the sub-acute, and the acute.

Chronic form. The origin is rather insidious, the individual being susceptible to "colds," or "catarrhs," on the slightest exposure; gradually a persistent cough, with the expectoration of muco-pus, is established, each severe cold being accompanied with chill, fever, pain in the chest, and either slight hemorrhage or blood-streaked sputa. Finally, the catarrhal symptoms become persistent, with morning chills, evening fevers, and rather profuse night sweats, distressing cough, profuse muco-purulent sputa, containing the bacilli, great weakness and exhaustion, loss of appetite and feeble digestion, the symptoms growing persistently worse, death occurring from exhaustion after one or two years' duration.

Sub-acute variety. History of an acute attack of pneumonia of one or two weeks' duration, followed by a decided improvement, but not complete recovery. After a lapse of some weeks or months, symptoms of pulmonary softening begin, destroying the lung structure and forming cavities, accompanied by chills, fever, night sweats, emaciation, cough, muco-purulent and blood-streaked expectoration containing the bacilli, the patient dying from exhaustion within a year.

Acute variety, the so-called phthisis florida, runs a rapid course, beginning either as a croupous or catarrhal pneumonia, involving the whole of one or part of both lungs, associated with rapid loss of flesh and strength, high but variable temperature, 103°-105° F., with remissions, profuse night sweats, shortness of breath, severe cough, profuse, purulent and blood-streaked sputa containing the bacilli, loss of appetite, and feeble digestion, the patient succumbing in a few weeks or months, from exhaustion.

A decided remission in the local and general symptoms of the acute variety may occur, the disease afterward pursuing a more chronic course. Inspection. Shows deficient respiratory movements of the diseased portion of the lungs.

Palpation. Increased vocal fremitus over the consolidated lung tissue and cavities.

Percussion. The percussion note varies from a slight *impairment* of the normal note to *dulness*, and when cavities are formed, associated with scattered points of the *tympanitic* or *hollow* note. If the cavities communicate with a bronchial tube the *cracked-pot* or *cracked-metal* sound is elicited. If the cavities are filled with pus the percussion note is *dull*. If the pus be expelled, the tympanic or cracked-pot sound returns.

Auscultation. The vesicular murmur is unimpaired in those parts free from disease: it is *feeble* or indistinct if many bronchioles are obstructed; and is harsh or *blowing* if the bronchioles are narrowed. The *inspiratory* sound will be *jerking*, and the *expiratory* sound *prolonged* and *blowing* when the lung has lost its elasticity.

Associated with the impaired vesicular murmur is a fine, dry, crack-ling sound (crepitation), appearing at the end of inspiration. If bronchitis be associated, large and small moist or bubbling râles are also heard during respiration.

When cavities form, either bronchial or broncho-cavernous respiration is heard, associated with more or less distinct gurgling râles. If the cavity be free from pus and have rather firm walls, the breathing is more amphoric in character.

Diagnosis. Catarrhal bronchitis has many points of resemblance to pneumonic phthisis. The subsequent course of the latter, with the high temperature, prostration, emaciation, sputa containing bacilli, and physical signs will prevent error.

Acute fibrinous and catarrhal pneumonia, often after a course of two or three weeks, show the bacilli and yet are not recognized as tuberculosis. It is a safe rule of practice to suspect tuberculosis and examine daily for the bacilli, in all cases of pneumonia that show the least tendency to linger, and particularly where there are chills and a remittent temperature record.

Prognosis. Acute variety, the phthisis florida, usually terminates fatally within a few months.

The *sub-acute* and *chronic* varieties may, under judicious treatment and favorable hygienic conditions, be arrested, the caseous matter partly expectorated and partly absorbed, leaving more or less loss of

structure, cicatricial tissue supplying its place, which after a time contracts, causing more or less retraction of the chest walls.

Cases not properly treated, either from carelessness or poverty, succumb after a year or two.

TUBERCULAR PHTHISIS.

Synonyms. Tuberculosis; consumption; incipient phthisis; chronic phthisis; chronic ulcerative phthisis.

Definition. A chronic pulmonary disease caused by the bacillus tuberculosis, resulting in the deposition of tubercle in the lung structure, which in turn undergoes ulceration and softening which results in a septic infection, characterized by progressive failure of health, fever, cough, dyspnæa, emaciation and exhaustion.

Causes. Hereditary and acquired susceptibility to the influence of the bacillus tuberculosis. It is questionable if an individual is born with pulmonary tuberculosis, or makes his advent with tissues that are a congenial soil for the growth and ravages of this wide-spread germ. Amongst the acquired causes are syphilis, alcoholism, chronic nephritis, certain occupations, and living in damp, overcrowded, dark and illy ventilated locations. Debility following an attack of influenza, predisposes to the deposition of tubercle.

Pathological Anatomy. Tubercle is a grayish-white, translucent and semi-solid granulation, about the size of a millet seed, most commonly deposited in the walls of the bronchioles, exciting a low form of inflammation, the result of its own death. The masses of tubercle soon undergo softening (cheesy transformation); the lung structure is secondarily affected, undergoes softening, which results in more or less destruction of the tissue, whence cavities are formed.

The inflammation may extend to the small arteries, causing hemorrhage.

The deposit of tubercle is generally at one of the apices, and "once present in an apex, the disease usually extends in time to the opposite upper lobe; but not, as a rule, until the apex of the lower lobe of the lung first affected has been attacked. Lesions of the base may be primary, though this is rare." Depositions may also occur in the brain, intestines and liver.

The pleura is usually the seat of a chronic inflammation (dry pleurisy, tubercular), resulting in the obliteration of the pleural cavity.

Symptoms. The symptoms correspond closely to the stages of deposition, of softening, septic infection, and of the formation of cavities.

The development is *insidious*, with increasing *dyspepsia* and *anamia*, the loss of appetite, distress after meals, and feeling of weakness, often misleading the patient and physician for some time until the occurrence of an *irritable heart*, a slight, dry, hacking *cough*, referred to the throat or stomach, scanty, glairy *expectoration*, gradual *loss of weight*, impaired muscular *strength*, *pallid appearance*, and a more or less copious *hamoptysis*. *Pain*, sharp in character, below the clavicles, is often present. These symptoms are characteristic of the development of the disease.

The beginning of softening is announced by increased cough, freer expectoration, showing under the microscope the bacilli, dyspnwa increased on exertion, morning chills, evening fever, night sweats—the so-called hectic fever, diarrhwa, increased emaciation and weakness, the patient, however, continuing very hopeful.

With the formation of the cavities, the cough is more aggravated, with profuse and purulent expectoration, at times containing yellow striæ, the amount depending upon the number and size of the cavities; hæmoptysis is not common at this stage; the pulse rapid and weak, increased hectic, burning of the soles and palms, copious night sweats, greater debility and emaciation, with ædema of the feet and ankles, denoting failure of the circulation, death soon following from asthenia, the mind clear and hopeful to the end.

Inspection. First stage, often shows slight depressions in the supra-clavicular, and at times in the infra-clavicular regions.

Palpation. Second stage, the vocal fremitus is slightly increased. Percussion. First stage, slight impairment of the normal percussion resonance can sometimes be elicited. Second stage, the resonance is impaired, and may be even dull. Third stage, dulness with circumscribed spots of the amphoric, or tympanitic or cracked-pot sound.

Auscultation. First stage, inspiration jerky, expiration prolonged, the pitch higher than normal, the inspiration associated with crackling râles.

Second stage, vesico-bronchial breathing, associated with sub-crepitant and large and moist or bubbling râles.

Third stage, bronchial, broncho-cavernous and cavernous respira-

tion, associated with large and small moist or bubbling, and localized gurgling râles.

Bronchophony in its various degrees is associated with the second

and third stages of tuberculosis.

Complications. Tubercular diseases of the brain, larynx, pleura, intestines and peritoneum; perineal abscess leading to fistula, endocarditis and myocarditis.

Diagnosis. The early diagnosis of tubercular phthisis rests mainly on the history, together with the symptoms and physical signs. In the first stage it is often mistaken for dyspepsia, anæmia, malarial fever, or disease of the heart; if the bacilli can be found in the sputum the diagnosis is settled.

Prognosis. In the main unfavorable, although under proper treatment, change of climate and like favorable conditions, life may be prolonged for years.

FIBROID PHTHISIS.

Synonyms. Chronic interstitial pneumonia; cirrhosis of the lungs; Corrigan's disease.

Definition. A hyperplasia (thickening) of the pulmonary connective tissue, resulting in atrophy and degeneration of the vesicular structure, associated with bronchial inflammation; characterized by cough, profuse expectoration containing the bacillus tuberculosis, fever, emaciation, and ultimately death by asthenia.

Causes. Hereditary predisposition; inhalation of irritants and associated with certain occupations, such as stone-cutters, grinders, etc. Following lobar pneumonia; chronic bronchitis; alcoholism; syphilis; chronic nephritis.

Pathological Anatomy. Thickening of the bronchial mucous membrane and dilatation of the air tubes; hyperplasia of the pulmonary connective tissue, resulting in the compression and consequent destruction of the vesicular structure, which is assisted by the contraction of the newly formed tissues. Sooner or later catarrhal pneumonia results, the product undergoing the cheesy degeneration, cavities being formed, and as a result of the long-continued suppuration, tubercular depositions occur, hastening the destruction of the lung tissue.

Prof. Da Costa has reported a number of cases of "grinders' phthisis," in whose sputum was found the "bacillus tuberculosis," and in whose family history there were no traces of consumption.

Symptoms. The course is chronic, beginning as a bronchial

catarrh, worse in winter, better in summer, when, after several years, the cough becomes more continuous, the expectoration freer and muco-purulent, containing the bacillus tuberculosis in large numbers, hectic fever develops, night sweats, dyspnwa, and rapid emaciation, soon followed by wdema of the feet and ankles, the result of failing circulation, death occurring by asthenia.

Inspection. Depression of the chest walls.

Percussion. *Impaired* resonance, followed by *dulness*, with irregular spots of amphoric or *tympanitic* percussion note over the points of depression.

Auscultation. First stage, vesiculo-bronchial, or harsh respiration associated with large and small, moist or bubbling râles, followed by bronchial, broncho-cavernous, and cavernous respiration, with circumscribed gurgling râles.

Diagnosis. Beginning as a bronchial catarrh, slowly progressing, with the remission of the symptoms during the summer months, finally becoming progressively worse, the discovery of the bacilli in the sputum, with the formation of cavities, and symptoms of asthenia, are the chief points in the diagnosis.

Prognosis. The duration of fibroid phthisis is most protracted, six to twelve years being the average duration; death, however, is the inevitable termination.

Prof. Da Costa has records of one hundred deaths from "grinders' consumption" whose average life was twelve years.

TREATMENT OF PULMONARY TUBERCULOSIS.

Can pulmonary tuberculosis be prevented? To a very great extent, yes, as in a large proportion of cases the *infection* of the system is the result of *contagion* or the ingestion of food containing the germ. The afflicted are not following the precepts of the Golden Rule, through ignorance of the laws of public hygiene. The medical profession is responsible for the lack of knowledge of the laity as to the dangers of consumptive patients. It is now known that tuberculosis is very common in the cattle, whose flesh forms such a large part of our food. Were it not for the protection given by cooking, the history of this disease would be a sadder one than it is. But the milk is not often cooked. May not the great increase in tuberculosis be caused by the use of cow's milk?

The bacilli once found in the sputum, can the unfortunate host be cured?

While I have never seen a case of incipient phthisis cured, in the broad acceptation of the term, I have repeatedly seen life prolonged for a number of years, and the deposition of tubercle long delayed by a change of climate early in the history of the case, warm clothing, life and exercise in the open air short of fatigue, and systematic bathing and a nutritious plan of dieting. If the diet is arranged in accordance with the appetite, the latter will gradually increase, but should it not, it may be stimulated by such bitters as strychninæ sulphas, nucis vomicæ, ignatia amara, colombo, or gentian.

The symptoms are to be met as they arise, and drugs are not to be used simply because the patient has the physical signs of beginning tubercle. For the general debility and malaise that accompanies the early stages of this malady, any one, or a combination of the following drugs, exercising care that they in no way interfere with the appetite: Guaiacol, gtts. iij-v, for adult, and gtts. ij-iij, for child, four times daily, in either sweetened water, milk, or meat broth, or wine; ol. morrhuæ, ferri iodidum, hypophosphites, elixir quininæ, ferri et strychninæ, or a combination of arsenicum and digitalis. (R. Acidi arseniosi, gr. j; digitalini (Merck's), gr. j. M. et ft. pil. No. xxx. Sig.—One after meals.)

In the *pneumonic variety* an attempt should always be made to remove the caseous matter by absorption and expectoration. The following prescriptions will sometimes prove successful:—

R.	Ammon. carb, Ammon. iodidi, Aq. chloroformi, Syr. prun. virg.,							gr. v–x f 3 ij	М.
Ever	y five hours, diluted, al								
R.	Liq. potassii arsenitis, Mass. ferri carb., Vini xerici, Aquæ dest.,		•				٠	gr. v f3j	М.

In the tubercular variety the early *dyspeptic* symptoms are wonderfully relieved by the following:—

R.	Pepsini cryst.,												gr. ij	
	Acid. hydrochl	orici	dil.	,				6	٠	٠			mxv	
	Glycerini													
	Succi limonis, .			٠	٠	٠	٠.	۰	٠	٠	۰	٠	mxv	
	Aquæ auranti f	lor.,		۰	2		ad	٠	٠	٠		٠	fgij.	M.
Cto	With mode													

It is in this variety of consumption that every means should be employed to improve the general health. Benefit may often follow from the long-continued moderate use of alcoholic stimulants, the amount being only such as will increase the appetite and improve the digestion. If rise of temperature, flushed face, or dyspeptic symptoms occur, discontinue the rum at once.

For the fibroid variety, to prevent the hyperplasia of the connective tissue, hydrargyri corrosivum chloridum, potassii iodidum, or aurii et sodii chloridum, are recommended. Oleum morrhuæ is of benefit.

For the gastric symptoms, which are often so severe as to seriously interefere with assimilation, either bismuth, gr. xx before meals, or salol, gr. j-ij, or arsenicum. (R. Liquor. potassii arsenitis, mxxx, tincturæ nucis vomicæ, f3j, aquæ chloroformi, ad f3ij. M. Sig.—Teaspoonful before meals.)

For the *fever*, unfortunately, but little can be accomplished with drugs. If, however, it exceeds 101° F., an attempt should be made to reduce it.

The "Niemeyer pill" is usually recommended, its formula being-

R.	Quininæ sulph.,	۰	٠			٠			٠	۰				٠	gr.	j	
	Pulv. digitalis.,	٠	0	•	٠				٠		٠	۰			gr.	SS	
	Pulv. opii,		۰										0		gr.	1/4	
	Pulv. ipecac, .		٠	٠		٠		٠	٠		۰	۰	0	۰	gr.	1/4 -	Μ.

From a very considerable experience with this "famous" pill, I can recall few cases in which it has proven of the least benefit. The following is much more effectual:—

R.	Quininæ sulph., .													. gr. x	
	Quininæ muriat.,		٠			٠	٠	٠	٠	٠	٠	٠	٠	. gr. x	M.
F	Pulv. opii et ipecae	3.,	۰	٠	۰	۰	*	۰	٠	٠	*	۰	٠	. gr. nj.	TAT *

S1G.—One capsule five hours, and the other three hours before the decided rise of temperature.

In a few instances the temperature has been favorably influenced by antifebrin gr. v, in tablets at one, three, and five o'clock each afternoon, or acetanilidum, gr. v, at the same hours. If sweating occur, add to each five-grain tablet agaricin gr. $\frac{1}{30}$. Many patients prefer cool sponging, adding alcohol, vinegar, or bay-rum to the water, and there is no doubt but that sponging will promptly reduce the temperature, two or three degrees.

For the cough either of the following are of use:-

R.	Codeinæ sulphat.,						٠		gr. 1/3-1/2	
	Acidi hydrocyanici dil				- 0			0	[[]	M.
	Syr. tolu,	۰		۰	۰	٠			13).	12.5
SIC	—Several times a day.									

Or-

В.	Ammonii chloridi,	
2,00	Sots, frumenti,	
	Glycerini, f z iv	
	Tincturæ opii camphorat.,	
	Aquæ chloroformi,	
	Syr. prun. virg., ad f \bar{z} vj.	M.
Sig	Dessertspoonful every four or five hours, with water.	

If diarrhaa develop, bismuth, gr. xx-xxx every three or four hours, with rest in bed and mustard to the abdomen, or &. Cupri sulphat, gr. jss; ext. nucis vom., gr. jij; pulv. opii, gr. vj. M. et ft. pil. No. xij. Sig.—One every three or four hours; or, &. Liquor. potassii arsenitis, mxxx; tincture opii deodorat., f3jss; liquor pepsini, ad f3jj. M. Sig.—Teaspoonful at meal time.

For night sweats, atropine sulphas., gr. $\frac{1}{00}$, at bedtime, or agaricine, gr. $\frac{1}{20}-\frac{1}{10}$, at bedtime, adding small dose of morphina if it cause loose stools. Camphoric acid, gr. xx-xxx, about two hours before the expected sweat; the time of administration is important, as the drug is rapidly eliminated. It has the additional advantage of causing no ill or disagreeable effect. It is best given dry on tongue. It is claimed that sulphonal, gr. vij-x, at bedtime, controls the night sweats and also produces a quiet, refreshing sleep.

For hæmoptysis no one remedy is comparable with atropinæ sulphas, gr. $\frac{1}{200}$ $\frac{1}{100}$ $\frac{1}{00}$ hypodermically repeated pro re nata.

Beginning in December, 1890, a large number of cases of incipient tuberculosis were treated in the wards of the Philadelphia Hospital with Koch's tuberculin. The treatment was negative in every case. In the fall of 1892 ten cases of early tuberculosis were placed under treatment with Kleb's tuberculocidin. Its action is different from Koch's tuberculin in that it never excites the febrile reaction of the latter. The results are thus far encouraging, as there is a lull in the symptoms in each case.

Creosotum and guaiacol have not proven their specific properties. The diet must be of the most nutritious and easily digestible

character. If oleum morrhuæ or petrolatum can be assimilated, either should be used for a long time. The hygiene of the patient is of the utmost importance, and as it is a struggle for life, no means should be left untried to gain the victory.

DISEASES OF THE PLEURA.

PLEURISY.

Synonyms. Pleuritis; "stitch in the side."

Definition. A fibrinous inflammation of the pleura, either acute, subacute or chronic in character, occurring either idiopathically or secondarily; characterized by a sharp pain in the side, a dry cough, dyspnœa, and fever. It may be limited to a part, or may involve the whole of one or both pleural membranes.

Causes. *Idiopathic* pleuritis is said to be due to cold and exposure, to injuries of the chest walls, or the result of muscular exertion. Tuberculosis is the cause of a few acute pleurisies.

Secondary pleuritis occurs during an attack of pneumonia, pericarditis, rheumatism, variola, scarlatina, measles, Bright's disease, or puerperal fever.

Chronic pleurisy follows an acute attack, or is the result of tuberculosis, Bright's disease, or alcoholism.

Pathological Anatomy. The course pursued by an inflammation of a serous membrane is hyperamia followed by exudation of lymph, the effusion of fluid, its absorption, and the adhesion of the membranes.

The *first* or *dry stage* of pleurisy is a hyperæmia or diffused, irregular redness of the membrane, with little specks of exudation. The *second stage* is characterized by the copious exudation of lymph, more or less completely covering the membrane, giving it a dull, cloudy, or shaggy appearance. If the inflammation ceases at this point, it is termed *dry pleurisy*. The third, or stage of effusion, is characterized by the pouring out of a semi-fibrinous liquid; more or less completely filling and distending the pleural cavity, and floating in the fluid are fibrinous flocculi, blood, and epithelial cells.

Absorption of the fluid and more or less of the exudative lymph soon occurs, the unabsorbed portion becoming organized, forming

adhesions which obliterate the pleural cavity.

The effusion, if on the right side, pushes the heart further to the left; if on the left side, the heart is displaced to the right, the impulse often being seen to the right of the sternum. The lungs are also compressed and displaced upward and against the spinal column, and, on removal of the fluid, expand again, except in cases of chronic pleurisy, when the functional activity of the pulmonary structure is more or less permanently impaired.

Chronic pleurisy results when the fluid is not absorbed or when it is effused into the cavity in a slow and insidious manner. The membrane is irregularly thickened, with firm adhesions, fluid being found in the meshes; depressions of the thoracic walls also occur. The fluid may be serum, pus (empyema), or pus and blood. Openings may form, through which there is a permanent discharge, either externally (fistulous empyema) or into the bronchi, or, rarely, into the bowels

Symptoms. Acute variety: Begins with a chill, followed by a sharp lancinating pain (stitch) near the nipple or in the axilla, aggravated by coughing and breathing, associated with slight tenderness on pressure. The respirations are rapid and shallow, 30–35 per minute, a short, dry, hacking cough, moderate fever, compressible pulse, 90–120. With the effusion of liquid the dyspnwa becomes aggravated, the cough more distressing, the cardiac action embarrassed, the countenance wearing an anxious expression, the patient usually lying on the affected side. With the absorption of the fluid the symptoms gradually ameliorate, convalescence being more or less rapid.

Subacute variety: Begins insidiously after cold, exposure, and fatigue in those enfeebled. Patients usually complain of a sense of veariness, shortness of breath, aggravated on exertion, evening fever, followed by night sweats, short, harassing cough, none or very scanty sputum; the pulse is small, feeble, but frequent, 100–120 beats per minute. The characteristic pain in the side is usually wanting.

Chronic variety, irregular chills, fever, night sweats, dyspn@a, palpitation, embarrassed circulation, with more or less prostration.

Inspection. First stage, deficient movement of the affected side, on account of the pain induced by full breathing.

Second stage, bulging or fullness of the affected side, with oblitera-

tion of the intercostal spaces and displacement of the cardiac impulse.

Palpation. Second stage, vocal fremitus feeble or absent over the site of the effusion, exaggerated above the site of the fluid. Rarely, fluctuation may be obtained.

Percussion. First stage, may be slightly impaired.

Second stage, dulness or even flatness over the site of the effusion; tympanitic percussion note above the fluid.

Auscultation. First stage, feeble vesicular murmur over the affected side, the patient breathing superficially, to prevent the pain; a friction sound, slight and grating or creaking, becoming louder as the exudation of lymph increases, limited usually to the angle of the scapula of the affected side, rarely heard over the entire side, accompanies the respiratory movements.

Second stage, feeble or absent vesicular murmur on the affected side, depending upon partial or complete compression of the lungs by the fluid. Above the fluid puerile breathing, and just at the upper margin of the fluid a friction sound may be heard.

The vocal resonance is diminished or absent over the site of the fluid and markedly increased above, agophony being present at the upper margin of the fluid.

With the absorption of the fluid the vesicular murmur gradually returns, associated with a moist friction sound.

Diagnosis. Acute pneumonia is often mistaken for the effusion stage of pleurisy. The points of distinction are, in pneumonia there is the pronounced chill, high fever, and characteristic sputa, bronchial breathing, exaggerated vocal fremitus and resonance, and no displacement of the heart, the reverse occuring in pleurisy.

Enlargement of the liver may be mistaken for pleurisy with effusion, the chief point of distinction being that, in enlargement of the liver, the superior line of dulness is depressed upon full inspiration, while in pleurisy with effusion inspiration does not modify the location of the dulness.

Prognosis. *Idiopathic* pleurisy usually terminates in recovery within three weeks. Pleurisy the result of constitutional causes has its prognosis modified by the condition with which it is associated. *Empyema*, unless the result of a diathesis, terminates favorably. *Double pleurisy is unfavorable*. The etiological factor of tuberculosis

must always be borne in mind in making a prognosis in pleurisy, whether acute or chronic.

Treatment. At the onset, in plethoric patients, wet cups over the affected side; if great dyspnæa, severe pain and high arterial tension, even venesection, and in anæmic or weak persons, dry cups, following the use of either the wet or dry cups with poultices or turpentine stupes. The severe pain is promptly relieved by the hypodermic injection of morphinæ sulphas, over its site, repeated as indicated, or the frequent use of small doses of pulvis ipecacuanhæ et opii.

In the very early stages of pleurisy the disease may be cut short by sodii salicylas, gr. xv-xx, well diluted, every three or four hours. In the stage of effusion excellent results follow the use of the salicylates.

Salol, gr. x every three or four hours, is sometimes useful early in the disease.

After effusion has begun extractum pilocarpi fluidum, gtt. xx, every two or three hours, or in drachm doses every other day for a week or two, after which twice weekly; or—

R. Potassii acetat., gr. xxx
Infus. digitalis, f z ij. M.
Every three or four hours.

Bowditch, of Boston, for years has advocated early aspiration in pleural effusion. If after three or four days no impression is made on the effusion by drugs, aspiration should be employed and table-spoonful doses of *liquor ferri et ammonii acetatis* (Basham's mixture) administered every four hours, and an early morning dose of magnesii sulphas, \$\frac{7}{3}\$ss-i.

The effusion of pleuritis is rapidly removed by the method of treatment suggested by Prof. Matthew Hay, of Scotland, consisting in the use of a concentrated solution of saline cathartics: "Order the patient to take nothing after the evening meal, and then, an hour or so before breakfast, the salt is given dissolved in as little water as possible. Usual dose from 3iv-vj to 3j-ij magnesii sulphatis to an ounce or two of water, no fluids to be used after the dose; this usually produces from four to eight watery stools, without pain or discomfort, and also acts as a diuretic."

The essence of the "Hay method" consists in getting the concentrated solution into the intestines at a time when the fluid contents are scanty.

If the effusion is uninfluenced by the above named means, use potassii iodidum, gr. xv, every four hours, well diluted, with flying blisters over the affected side, or unguentum hydrargyri in the armpits, groins, and over the site of the effusion.

In double pleuritic effusion, evacuate the fluid at once with the aspirator, and use the potassium and digitalis mixture mentioned above.

Chronic pleurisy: if the effusion be still serous, it is often absorbed by the internal use of potassii iodidum, alternating with "Basham's mixture," and blisters, the secretions being watched. If, however, the liquid is pus (empyema), the aspirator should be used at once, the patient placed upon "Basham's mixture," stimulants and quinina.

Usually, however, within a very few days after aspiration, another accumulation of pus will have taken place. Should this occur, the purulent pleurisy should then be treated as an abscess, an incision being made between the fifth and sixth ribs, the pus evacuated, a drainage tube introduced, and an antiseptic dressing applied. If the tendency to pus secretion still remains, the pleural cavity must be washed out with an antiseptic solution, the constitutional treatment being continued.

HYDROTHORAX.

Synonym. Dropsy of the pleura.

Definition. The effusion of fluid into the pleural cavities (bilateral), the result of a general dropsy from renal or cardiac disease.

Pathological Anatomy. More or less clear serous fluid in both pleural sacs, compressing the lung. No signs of inflammation are present.

Symptoms. Following dropsy of the abdomen occurs dyspnaa, with signs of deficient blood aëration, both lungs being compressed.

Palpation. Absent vocal fremitus over the site of the fluid.

Percussion. Dulness over the site of the fluid.

Auscultation. Absent vesicular murmur over the site of the fluid.

Diagnosis. Easily determined by association of the symptoms with a general dropsy.

Prognosis. Controlled by the cause producing the general dropsy.

Treatment. Depending upon the condition causing the dropsy. Dry cups over the chest afford relief. If the symptoms of non-aëration of the blood are severe, the fluid should be at once evacuated with the aspirator.

PNEUMOTHORAX.

Synonyms. Air in the pleural cavity; hydropneumothorax.

Definition. The accumulation of air in the pleural cavities, with the consequent development of inflammation of the membranes; characterized by sharp pain, followed by rapidly developing dyspnæa and cough.

Causes. Generally the result of tubercular phthisis, causing perforation of the pleura. Perforation may take place from the pleura into the lung, in connection with empyema or abscess of the chest walls. Direct perforation from without, by laceration of a fractured rib or severe contusion.

Pathological Anatomy. The gas in the pleural cavity consists of oxygen, carbon anhydride, and nitrogen in variable proportions. It may fill the pleural sac completely, compressing the lung, or is sometimes limited by adhesions. The gas tends to excite inflammation, the resulting effusion being either serous or purulent.

Symptoms. Symptoms of pneumothorax, the result of perforation, are *sudden or sharp pain* in the side, *intense dyspnwa*, attended with symptoms of *collapse*, coldness of the surface, and cold sweats.

The above symptoms, in many instances, follow a severe or violent paroxysm of *coughing*. In severe cases there is never a moment's cessation of the acute pain and distressing dyspnæa, causing orthopnæa from the onset until death.

Inspection. Enlargement of the affected side, the intercostal spaces being widened and effaced or even bulged out so that the surface of the chest is smooth. Respiratory movements of the affected side are diminished or absent.

Percussion. Immediately after the rupture the percussion note is hyper-resonant, or even tympanitic or amphoric in quality. If the amount of air in the pleural cavity becomes extreme, there is dulness on percussion, associated with a feeling of great resistance or density. When effusion of blood occurs, dulness is observed over the lower part of the chest, hyper-resonant or tympanitic percussion note over the upper portions of the chest, these sounds changing as the patient changes position.

Auscultation. The normal vesicular murmur may be diminished

or absent. The typical amphoric respiratory sound is heard when the fistula is open, usually associated with a metallic echo.

Metallic tinkling, or the bell sound, is sometimes distinctly produced by breathing, coughing or speaking, after the development of inflammation of the pleura.

The vocal resonance may be diminished or absent, or, rarely, it may be exaggerated, with a distinct metallic echo.

After the development of inflammation in the pleura, suddenly shaking the patient gives rise to a *splashing sensation*, the succussion sound, if both air and fluid are present in the pleural cavity.

Prognosis. When occurring as the result of tuberculosis, the prognosis is extremely unfavorable; rarely, the fistulous opening being enclosed by inflammatory action; the case then becomes one of chronic pleurisy.

Treatment. At once a hypodermic injection of *morphina* sulphas, which relieves the severe pain and somewhat modifies the distressing dyspnæa, followed by the evacuation of the fluid and air with the aspirator.

If the fistulous opening be closed by inflammatory action, the case resolves itself into one of chronic pleurisy, the treatment indicated for that affection plus the treatment of tuberculosis, being the indication.

DISEASES OF THE CIRCULATORY SYSTEM.

The methods employed in making a physical examination of the heart are: I. Inspection. II. Palpation. III. Percussion. IV. Auscultation.

Inspection indicates the exact point of the cardiac impulse, and the presence or absence of any abnormal pulsations or any change in the form of the pracordium.

Normally the *impulse* is visible only in the *fifth interspace*, midway between the left nipple and the left border of the sternum, its area covering about one square inch, most distinct in the thin, while often barely seen in the very fleshy; often displaced downward by full inspiration and elevated by complete expiration.

Disease may alter the position and area of the impulse.

The position of the impulse is moved to the right by left pleuritic effusions; downward by cardiac hypertrophy or pulmonary emphysema; upward by a pericardial effusion.

The area of the impulse is changed and enlarged by pericardial

adhesions, cardiac dilatation, or hypertrophy.

Palpation confirms the observations of inspection, and also determines the force, frequency and regularity of the cardiac impulse.

The force of the *impulse* is *diminished* by cardiac dilatation, fatty and fibroid degenerations of the heart, emphysema, pericardial effusion, and adynamic diseases.

The *impulse* is *increased* by cardiac hypertrophy, during the first stage of endocarditis and pericarditis, functional cardiac disturbances and sthenic inflammations.

Percussion will determine the boundaries of the superficial and deep cardiac space, the so-called pracordium. It is essential that the upper, lower, and two lateral boundaries of the pericardial region be memorized, to wit: superior boundary, the upper edge of the third rib; the lower boundary is a horizontal line passing through the fifth intercostal space; the left lateral boundary is about or a little within a vertical line passing through the nipple, the linea mammalis; and the right lateral boundary is an imaginary vertical line situated one-half an inch to the right of the sternum. These boundaries vary somewhat in health, but are sufficiently accurate for all practical purposes.

The superficial cardiac space represents that portion of the heart uncovered with lung; it is triangular in form, its apex being the junction of the lower border of the left third rib with the sternum, its area not exceeding two inches in any direction.

The superficial space is *increased* by cardiac hypertrophy, dilatation or pericardial effusion.

Diminished at the end of full inspiration or by emphysema.

The deep cardiac space represents that portion of the heart covered by lung, and extends from the upper border of the third rib to the lower edge of the fifth interspace, and from half an inch to the right of the sternum to near the left nipple.

It is *increased* by hypertrophy or dilatation of the heart, left pleuritic effusion, and apparently increased by consolidation of the anterior border of the investing lung.

Auscultation indicates the character of the normal cardiac sounds, and the point at which they are heard with greatest intensity, and should be thoroughly familiarized if abnormal sounds are to be fully appreciated.

The ear or stethoscope applied to the præcordium distinguishes in health, two sounds, separated by a momentary silence—the short pause, and the second sound followed by an interval of silence—the long pause.

The first sound, corresponding to the contraction of the heart—the systole—is louder, longer, and of a lower pitch and a more booming quality than the second sound, and has its point of greatest intensity at the cardiac apex or a little to the left. It corresponds closely in time to the pulsations as felt in the carotid or radial arteries.

The second sound is shorter, weaker, and higher in pitch than the first sound, and has a clicking or valvular quality, having its point of greatest intensity at the second right costal cartilage and a little above, and corresponds to the closure of the aortic and pulmonary valves. The sound made by the closure of the tricuspid valves is best isolated at the ensiform cartilage. The sound made by the closure of the pulmonary valves at the third left costal cartilage.

The extent of surface over which the cardiac sounds are heard varies, according to the size of the heart and the condition of the adjacent organs for transmitting sounds.

The cardiac sounds may be altered in *intensity*, *quality*, *pitch*, *seat* and *rhythm*, or they may be accompanied, preceded, or followed by adventitious or new sounds, the so-called *endocardial or cardiac murmurs*.

The intensity is increased by cardiac hypertrophy, irritability of the heart or consolidation of adjacent lung structure.

The intensity is diminished by cardiac dilatation or degeneration, during the course of adynamic fevers, emphysematous lung overlapping the heart, or pericardial effusion.

The quality and pitch of the first sound may be sharp or short and of higher pitch when the ventricular walls are thin, or have undergone beginning fibroid change, the valves being normal; its pitch and quality are also raised during the course of low fevers. The second sound becomes duller and lower in pitch when the elasticity of the aorta is diminished or the aortic valves thickened. Either or

both sounds have a more or less metallic quality in irritable heart and during gaseous distention of the stomach.

The seat of greatest intensity of the cardiac sounds is changed by displacement of the heart, pleuritic effusion, pericardial effusion, and abdominal tympanites.

The rhythm is often interrupted by a sudden pause or silence, the heart missing a beat, or the sounds are irregular, confused and tumultuous, the result of organic changes in the cardiac muscle, valves, or orifices; or a reduplication of one or both sounds of the heart may occur.

The adventitious cardiac sounds or murmurs are of two kinds, those made external to the heart, as pericardial, exocardial, or frictional murmurs, and those made within the cardiac cavity, endocardial murmurs.

Pericardial mumurs, or friction sounds, are made by the rubbing upon one another of the roughened surfaces of the pericardial membrane during the early stages of inflammation. The sounds have a rubbing, creaking, or grating character, and are differentiated from a pleural friction sound by their being limited to the præcordium, synchronous with every sound of the heart, and not influenced by respiration.

They are distinguished from an endocardial murmur by their superficial rubbing, creaking or grating character, and by not being transmitted beyond the limits of the heart, either along the course of the vessels, or to the left axilla, or back.

Endocardial murmurs are of two kinds, to wit: organic and functional.

Functional endocardial or blood murmurs are the result of changes in the natural constituents of the blood.

Their character is soft, they are heard most distinctly at the base to the left of the sternum, during the systole, are not transmitted beyond the limits of the heart, either to the left axilla or the back, and are associated with general anæmia.

Organic endocardial murmurs are produced by blood currents pursuing either a normal or an abnormal direction.

In health there are two direct blood currents upon each side of the heart, to wit: the current from the left auricle to the left ventricle, the mitral direct current; the current from the left ventricle to the aorta, the aortic direct current; the current from the right auricle to the right

ventricle, the tricuspid direct current, and the current from the right ventricle to the pulmonary artery, the pulmonic direct current.

When, from disease, the valves are not properly closed, the blood is allowed to flow back against the direct current producing abnormal blood currents, to wit: when the mitral valve is incompetent, the blood flows from the left ventricle back into the left auricle during the cardiac systole, producing the *mitral regurgitant or indirect current*; when the aortic valves are incompetent, the blood is permitted to flow from the aortic regurgitant or indirect current; when the tricuspid valves are incompetent, the blood flows from the right ventricle back into the right auricle during the systole, producing the *tricuspid regurgitant or indirect current*; when the pulmonary valves are incompetent, the blood flows from the pulmonary artery into the right ventricle, producing the *pulmonic regurgitant or indirect current*.

The mitral direct current occurs during the contraction of the left auricle, or just before the first sound of the heart and immediately after its second sound. The aortic direct current is produced by the contraction of the left ventricle, and occurs with the first sound of the heart. The tricuspid direct current occurs during the contraction of the right auricle, or just before the first or immediately after the second sound. The pulmonic direct current is produced by the contraction of the right ventricle, occurring during its first sound.

The mitral direct, or presystolic murmur, occurs before the first sound of the heart and immediately after the second sound. It is caused by a narrowing of the mitral orifice, has a blubbering quality, well imitated by throwing the lips into vibration by the breath, of a low pitch, and it has its seat of greatest intensity at the cardiac apex, and is not transmitted to the left axilla or to the base of the heart.

The mitral regurgitant, or systolic murmur, occurs with the first sound of the heart, resulting from the failure of the mitral valves to close the mitral orifice during the systole, in consequence of which the blood flows back, or regurgitates into the left auricle. It is usually of a blowing or churning character, and has its seat of greatest intensity at the cardiac apex, being well transmitted to the left axilla and inferior angle of the left scapula.

The aortic direct murmur occurs with the first sound of the heart. It is caused by a narrowing of the aortic orifice, has a rough or creak-

ing character, is of high pitch, having its seat of greatest intensity in the second intercostal space, to the right of the sternum, and is well transmitted over the carotid artery.

The aortic regurgitant murmur occurs with the second sound of the heart, and is caused by the failure of the aortic valves to close the aortic orifice during the diastole, permitting the blood to flow back or regurgitate into the left ventricle. It is usually of a blowing or churning character and of low pitch, having its seat of greatest intensity over the base of the heart, and is well transmitted downward toward or below the cardiac apex. It is the only organic murmur produced in the left side of the heart which occurs with the second sound of the heart.

The tricuspid direct murmur occurs before the first sound of the heart and immediately after the second sound. It is caused by a narrowing of the tricuspid orifice, has a blubbering quality, and is low in pitch, having its seat of greatest intensity near the ensiform cartilage. This murmur is exceedingly rare.

The tricuspid regurgitant murmur occurs with the first sound of the heart, the result of the failure of the tricuspid valves to close the tricuspid orifice during the systole, thus allowing the blood to flow back or regurgitate into the right auricle. It is usually of a blowing or soft, churning character, having its seat of greatest intensity at the ensiform cartilage. This murmur is also very infrequent, and occurs mostly when the right ventricle is considerably dilated, and without the existence of any valvular disease.

The pulmonic direct murmur occurs with the first sound of the heart. It is generally connected with congenital lesions. It occurs at the same instant that the aortic direct murmur occurs, and is distinguished from the latter by its not being transmitted into the carotid artery, whereas the aortic direct murmur is always thus transmitted.

The pulmonic regurgitant murmur occurs, like the aortic regurgitant murmur, with the second sound of the heart. This murmur is exceedingly rare, and its presence is only positively differentiated from the aortic regurgitant murmur by the absence of aortic lesions and symptoms.

ACUTE PERICARDITIS.

Definition. An acute fibrinous inflammation of the pericardium; characterized by slight fever, pain, præcordial distress and disturbed cardiac action and circulation.

If the inflammation be limited to the parietal or visceral layer, or to a part of either, it is termed *partial* or *circumscribed* pericarditis; if it involve the whole of both surfaces it is termed *general* or *diffused* pericarditis.

The inflammation may be primary or secondary.

Causes. Primary pericarditis is rare, resulting directly from cold and exposure or injuries.

Secondary pericarditis follows, or is associated with, rheumatism, influenza, scarlatina, variola, puerperal fever, tuberculosis, septicæmia, Bright's disease, gout, scurvy, and diabetes.

It is frequently associated with pneumonia and pleuro-pneumonia, particularly in alcoholics.

Pathological Anatomy. The same as of serous membranes in other situations. The morbid changes may be seen as (1), acute plastic, or dry pericarditis (frequently tubercular); (2), pericarditis with effusion, sero-fibrinous, hemorrhagic, or purulent.

Hyperamia of the membrane, most marked on the visceral layer, followed by the exudation of lymph scattered in irregular patches, giving it a rough and shaggy appearance (dry pericarditis), followed by the effusion of a sero-fibrinous fluid, with flocculi floating in it, and at times mixed with blood. Rarely, the fluid is purulent.

The fluid and lymph undergo absorption with resulting adhesions identical with those described under pleurisy.

Symptoms. Acute pericarditis may be well marked and still present none of the characteristic subjective symptoms. It usually begins with rigors, fever of the remittent type, frequently nausea and vomiting, pracordial distress, and tenderness, acute shooting pains, increased by breathing and coughing, dry, suppressed cough, increased cardiac action and sometimes violent palpitation. An attack of pericarditis secondary to an existing disease presents no marked symptoms other than those mentioned to indicate its onset. Attacks of nausea and vomiting occurring during the course of rheumatism, pneumonia, pleurisy and nephritis, should call attention to the heart. Duration of this early stage from a few hours to a day or two.

Effusion stage: the symptoms of this stage are in keeping with the amount and rapidity of the effusion: pracordial oppression, tendency to syncope, dyspnæa, sometimes amounting to orthopnæa, dysphagia, hiccough, nausea and vomiting, feeble, irregular pulse, sometimes either melancholia, delirium, or acute maniacal excitement.

Absorption is generally rapid, the heart remaining "irritable" for a long time after. If instead of absorption, the fluid accumulates, and life is not destroyed, the pericardial sac becomes dilated, chronic pericarditis resulting.

Inspection. Early stage, excited cardiac action is evidenced by the impulse.

Effusion stage, feeble, undulatory or absent impulse, its position displaced upward, or rarely, downward; bulging of the præcordium and protruding abdomen.

Palpation. Early stage, excited or tumultuous impulse; pericardial friction fremitus rare.

Effusion stage, feeble or absent impulse, and if present its position is changed.

Percussion. Early stage, normal.

Effusion stage, cardiac dulness enlarged vertically and laterally, and if considerable fluid, of a triangular shape, with the base of the triangle on a line with the sixth or seventh rib, extending from the right of the sternum to the left of the left nipple, narrowing as it proceeds upward to the second rib, or above, which represents the apex of the triangle. The shape of the dulness is sometimes altered by changing the position of the patient.

Auscultation. Early stage, excited cardiac action, and usually a friction sound (exocardial murmur) synchronous with cardiac sounds and uninfluenced by respiration, but often increased by pressure with the stethoscope.

Effusion stage, cardiac sounds feeble and deep-seated at the cardiac apex, becoming louder and distinct toward the cardiac base. The friction sound is sometimes heard at the cardiac base.

If absorption occur the above signs gradually give place to the normal, the friction sound returning, of a churning, or clicking, or grating character, gradually disappearing.

Diagnosis. *Endocarditis* is often confounded with pericarditis, the points of distinction between which will be pointed out when discussing that affection.

Cardiac hypertrophy or dilatation is sometimes confounded with pericardial effusion; the differences between which will be pointed out when discussing those affections.

Hydropericardium may be mistaken for pericardial effusion; see that affection.

Prognosis. Controlled by the severity of the inflammation, causes and coexisting affections. If slight effusion, favorable. Death has quickly occurred when a large quantity of fluid has been rapidly effused, the patient being really drowned in his own fluid. Adherent pericardium is a frequent sequela.

Treatment. Perfect rest in bed with absolute mental quiet. Death has followed neglect of this essential, and particularly during the stage of effusion.

The important indications for treatment are to limit the inflammatory action and quiet the heart in the first stage, and to promote absorption and prevent cardiac failure in the second stage.

Local applications in the early stage are most valuable; for vigorous patients, the application of *leeches* or *wet cups* to the præcordium, followed by the application of *ice* poultices or iced compresses; in the feeble, *dry cups* to the præcordium, followed by poultices.

For the gastro-intestinal symptoms calomel is indicated, and it may have a beneficial effect on the inflammatory action. (R. hydrargyri chloridi mitis, gr. 1/3; sodii bicarbonat., gr. ij; sac. lac., gr. ij; dry on tongue every two hours until free action.) Pepper says the "following combination is often very acceptable":

R.	Pulv. digitalis,										
	Mass. hydrargyri,			۰	0		ää			gr. x	
	Pulv. opii,										
	Quininæ sulph.,									gr. xxx.	M.
Ft	. mass et div. in pil	. 1	No.	. x	x.						
Sig.	-One pill three or	fc	our	tin	ne	s ć	laily.				

In young vigorous patients early in the disease control the excited cardiac action by small doses of aconitum or veratrum viride; in the adult, aged or feeble using digitalis; in all cases quinina is indicated. Avoid all cardiac sedatives in secondary cases save those following rheumatism.

Effusion stage: as the effusion progresses the free administration of alkalies, to wit: ammonii carb., gr. v, every two hours, with liquor

ammonii acetatis, or potassii acetatis, or potassii carbonatis, with quinina, nutritious liquid diet and stimulants, being cautious with the use of cardiac sedatives or tonics. If pain is prominent use morphina sulphas, hypodermically.

If the effusion has a tendency to linger, blisters to the præcordium, and potassii iodidum should be used, and if the symptoms of oppression are marked or the effusion linger, paracentesis is indicated. Dr. Roberts, in his monograph, gives an account of sixty cases of paracentesis with twenty-four recoveries. He advises that the tapping be done in the fossa between the ensiform and costal cartilages on the left side, or in the fifth left interspace near the junction of the sixth rib with its cartilage.

The diet must be nutritious and easy of digestion throughout the disease. If evidences of cardiac failure use strychninæ sulph., gr. $\frac{1}{25}$, hypodermically, three or four times daily.

CHRONIC PERICARDITIS.

Definition. A chronic inflammation of the pericardium, with either distention of the sac by fluid or adhesions of the pericardium (adherent pericardium); characterized by impaired cardiac action and disturbances of the circulation.

Causes. Almost always the result of an acute attack.

Pathological Anatomy. If the effusion be absorbed, the pericardial surfaces are agglutinated by several layers of lymph, which increase the thickness of the membranes half an inch or more, and the outer surface of the pericardium becomes adherent to the chest walls.

If the fluid be not absorbed it may progressively accumulate, distending the sac in all directions, displacing the diaphragm and interfering with the functions of the surrounding viscera, or a low grade of inflammation supervenes, the fluid becoming purulent, the disease terminating fatally after a variable period.

As much as eight to ten pints of fluid have accumulated in the sac. Symptoms. Pracordial pain and distress, irregular, feeble cardiac action, dyspnaa aggravated by movement and disturbed circulation.

An agglutinated pericardium seriously increases the danger from an attack of any pulmonary inflammation.

Inspection. If the effusion be present, bulging of the præcordium and displacement of the impulse.

If adhesions are formed between the pericardial surfaces as well as with the chest walls, inspection reveals depression of the pracordium, narrowing of the spaces, increased extent but displaced impulse, uninfluenced by deep inspiration, and recession of the intercostal spaces (systolic dimpling) and epigastrium with every systole of the heart, the result of the adhesions.

Palpation. If effusion, displaced, feeble or absent impulse; if adhesion, displaced and tumultuous impulse; occasionally a pericardial fremitus is distinguished.

Percussion. If effusion, the dulness has more or less the character described for acute pericarditis.

If adhesions, the cardiac dulness is but slightly modified.

Auscultation. If effusion, cardiac sounds feeble and deep-seated at the apex, louder and more distinct at the cardiac base.

If adhesions, cardiac sounds are heard with equal distinctness in their several positions, associated with a rough friction sound (exocardial murmur).

Treatment. If effusion, blisters to the præcordium, with potassii iodidum to hasten absorption, the patient being supported by nutritious diet, quinina, ferrum and stimulants, and perfect quiet. If these means fail to remove the fluid, or if the fluid be purulent, paracentesis should be performed at once.

If adhesions of the pericardium have resulted, the application of blisters to the præcordium with the administration of *potassii iodidum*, alternating with *ferrum* and *quinina* are indicated, with nutritious diet, stimulants and perfect quiet.

HYDRO-PERICARDIUM.

Synonym. Pericardial dropsy.

Definition. The accumulation of water in the pericardial sac, *minus* inflammation; characterized by præcordial distress, disturbed cardiac action, dyspnæa and dysphagia.

Causes. Usually a part of a general dropsy; Bright's diseases; sudden pneumothorax; pressure of an aneurism or other mediastinal tumor; disease or thrombosis of the cardiac veins.

Pathological Anatomy. The fluid may range in quantity from

an ounce to one or two pints, and is of a clear, yellowish or straw-colored serum, at times turbid or bloody, and of an alkaline reaction.

If the amount of fluid be large the sac is dilated, its walls thinned by the pressure, and has a sodden appearance.

Symptoms. Dropsy of the pericardium is so generally associated with hydrothorax that the symptoms are but an aggregation of those attending upon that condition, to wit: disturbed cardiac action, dyspnæa, dysphagia, dry cough, and feeble circulation.

The physical signs are exactly those of the stage of effusion of pericarditis, *minus* a friction sound.

Diagnosis. Pericarditis with effusion and hydro-pericardium present nearly the same signs and symptoms, a differentiation being possible only by a history of the case and the symptoms of the attack.

Prognosis. Controlled entirely by the cause.

Treatment. Depends upon the cause of the attack. If the amount of fluid in the pericardial sac be great, paracentesis will give relief.

ACUTE ENDOCARDITIS.

Synonyms. Valvulitis; exudative endocarditis.

Definition. An acute fibrinous inflammation of the serous membrane lining the cavity of the heart and forming its valves, in severe cases the chordæ tendineæ being involved, resulting in changes in the valves or orifices of the heart, or both; characterized by cough, dyspnæa, disturbed cardiac action, nausea, vomiting, and more or less marked febrile reaction.

Acute endocarditis occurs in two distinct forms: plastic or simple exudative endocarditis; ulcerous or diphtheritic endocarditis.

Causes. Usually secondary to acute articular rheumatism, pleuritis, pueumonia, pericarditis, Bright's disease, scarlatina, influenza, and diphtheria. The association of acute endocarditis and chorea is frequent.

While as yet no specific micro-organism has been discovered, the view is gaining that it is a microbic affection.

Pathological Anatomy. Inflammation of the endocardium is usually limited to the left side of the heart after birth, during feetal life the reverse being the case. The inflammation is limited or especially marked at the valvular portions of the endocardium, owing probably to the presence of fibrous tissue beneath the membrane in

these situations, and to the strain which falls upon the valves during the performance of their functions.

Hyperamia from congestion of the vessels beneath the membrane, with considerable swelling of the valves, the result of an exudation of lymph and scrum beneath and on the free surface of the membrane covering the valves and chordæ tendineæ, resulting in the roughening of the surfaces and the agglutination of the mitral valves to each other, and of the aortic segments to the walls of the aorta, or the proliferation of the endocardial connective tissue, forming the nuclei of the so-called warty excrescences or vegetations, their size being increased by the deposition of fibrin from the blood within the cavities of the heart.

These vegetations may be detached by friction, giving rise to *emboli* which may be washed by the blood current to the left side of the brain, or into the kidneys and the spleen.

In the ulcerative variety a process of softening takes place in the fibrinous deposits, leading to ulcerations and perforations.

Symptoms. This affection is usually masked by the course of another disease until disturbances of the circulation direct attention to the heart.

The onset is often by increase of temperature, pracordial distress, short cough, slight dyspnaa, more or less persistent vomiting, increased cardiac action, often rapid and tumultuous, with throbbing carotids and noises in the ear. As the inflammation progresses, the cardiac action and pulse decline in rapidity, with more or less congestion of the lungs and venous stasis.

Auscultation. Shows a change in the character of the sounds or the development of murmurs at the various orifices, the character and points of distinction between which will be pointed out when discussing valvular diseases of the heart.

Duration. Between one and three weeks.

Diagnosis. Unless it is a rule of practice to always auscult the heart, many cases will pass unobserved or undetected. *Pericarditis* is distinguished from endocarditis by the character of the physical signs. In pericarditis the murmur or friction sound is heard with either sound, is near to the ear and influenced by pressure of the stethoscope, besides being associated with more or less alteration in the size and shape of the cardiac dulness, and is not transmitted, while in endocarditis the murmur takes the place of, or is associated

with, the cardiac sounds, and is transmitted, with the absence of change or increased dulness on percussion.

If embolism occur, a new set of symptoms develop; embolism of the kidneys causes sudden, deep-seated lumbar pain, with albuminuria and even hæmaturia; embolism of the brain sudden palsies and sudden disturbance of consciousness; of the spleen, sharp pain and tenderness in the splenic region; of the skin petechial or purpuric spots.

Prognosis. Acute endocarditis is not very dangerous to life, hence a favorable prognosis may be given; regarding the ultimate results of valvular lesions, however, the prognosis is grave.

Treatment. Absolute rest in bed. At the onset leeches or wet cups to the præcordium, followed by ice, or, what may be preferable, poultices.

The excited circulation should be controlled by aconitum, veratrum viride, or digitalis.

The free administration of *alkalies*, to wit: *ammonii carbonas*, *potassii acetas* or *carbonas*, until the urine is decidedly alkaline, may prevent permanent changes in the valves or orifices.

If alkalies fail and the inflammation shows a tendency to linger, good results are often obtained by a slight hydrargyrum impression.

If signs of oppressed circulation appear, the hands becoming blue, the face and extremities ædematous, with congestion of the lungs, the free use of ammonii carbonas, digitalis, strophanthus, hypodermic injections of strychninæ sulphas, and stimulants are indicated. The free use of ammonii carbonas will often prevent or break up heart clots. After the acute symptoms have subsided, more or less absorption of the exuded lymph has followed the free use of potassii iodidum. During the entire course of the affection the diet should be of the most nutritious character.

MALIGNANT ENDOCARDITIS.

Synonyms. Ulcerative endocarditis; septic, mycotic, and diphtheritic endocarditis.

Definition. An acute *septic* inflammation of the lining membrane of the heart, with a strong tendency to ulceration; characterized by depression of the vital forces with more or less cardiac distress.

Causes. The specific micro-organism has not yet been determined. Frequently complicates pneumonia. Associated with ery-

sipelas and septicæmia. Rarely associated with acute rheumatism. Cases have been reported associated with or following influenza.

Pathological Anatomy. The changes are those of acute endocarditis up to the development of the thickening of the endocardium lining the valves, and the development of the vegetations. Instead of the poison spending its force and the chronic condition obtaining, a process of softening, ulceration, development of abscess and perforation of leaflets follows, resulting in loss of structure, general septic infection, and the development of emboli, which lead to infarctions, with their results in either brain, kidney, spleen, eye, or skin.

Symptoms. Vary greatly, but always associated with constitutional signs of sepsis—a typhoid state, such as headache, restlessness, varying delirium, coated, dry tongue, sordes on teeth and lips, nausea, vomiting, loose or disordered stools, enlarged spleen, albumin in urine and an irregular temperature record, varying from 100° F. to 104° F. or higher, associated with rigors and heavy sweating.

The cardiac action is rapid, irregular, and weak—a compressible pulse.

In the notes of twelve cases observed in the Philadelphia Hospital are the following symptoms: attacks of prolonged dyspnwa with paroxysms of intensity, or a slightly quickened respiration with paroxysms of dyspnwa occurring every few days. In four cases the paroxysms occurred three times daily with respirations under twenty-five between the paroxysms, for three weeks preceding death. Usually the respirations are so oppressed that the recumbent position is impossible for long periods. Another frequent symptom is marked cyanosis, either transient or lasting for days before the end.

A frequent symptom of ulcerative endocarditis is a peculiar facies, indicative of a sense of impending danger, great anxiety or terror.

If embolism occur, there are superadded symptoms varying with the organ affected. If the brain, rapid developing palsies with disorder of consciousness; if the kidneys, deep-seated lumbar pains with hæmaturia or disordered urinary flow; if the spleen, pain and tenderness of the splenic region with increase of temperature record.

Auscultation. The booming, muscular, first sound is superseded by a feeble, irregular cardiac pulsation. Generally, a murmur may be detected.

Diagnosis. One of the most difficult in medicine. Remember-

ing the diseases with which malignant endocarditis may occur and particularly pneumonia or sepsis, and the dyspnæa, the cyanosis, the facies, and the temperature record, it may be possible to diagnose the disease much more frequently than is done.

Prognosis. Unfavorable. Recovery the rarest termination.

Treatment. Entirely symptomatic. Nutritious diet, quininæ sulphas, ferrum, alcohol, strychninæ sulphas, strophanthus, caffeina, and digitalis. Local applications seem only to distress the patient, unless it be an emplastrum belladonnæ.

CHRONIC ENDOCARDITIS.

Synonyms. Sclerotic endocarditis; interstitial endocarditis; chronic valvular disease.

Definition. Alterations in the cardiac valves or orifices, rendering the former incapable of properly closing the orifices, or causing the narrowed orifice to interrupt the blood current in its normal movement.

The lesions are of two kinds: obstructive and regurgitant.

A regurgitant lesion, termed also insufficiency, is such change in the valves as to permit a portion of the blood to flow backward instead of onward, the true direction of the blood current.

An *obstructive lesion*, termed also *stenosis*, is a narrowing of the orifice, thereby obstructing the onward passage of the blood.

Varieties. I. Mitral regurgitation. II. Aortic regurgitation. III. Tricuspid regurgitation. IV. Pulmonic regurgitation. V. Mitral obstruction. VI. Aortic obstruction. VII. Tricuspid obstruction. VIII. Pulmonic obstruction.

Causes. The great majority of cases are the result of acute endocarditis following rheumatism, chorea or the infectious diseases. Chronic endocarditis from the onset is caused by alcoholism, syphilis, gout, and excessive muscular labor. Chronic Bright's diseases are also exciting causes.

Prof. Da Costa has clearly established the development of aortic disease in early life by overwork and strain of the heart.

In the elderly, chronic endocarditis is the result of atheromatous or fibroid changes.

MITRAL REGURGITATION.

This form, also termed insufficiency, is the most frequent of all the varieties.

Pathological Anatomy. The most common conditions observed are more or less contraction and narrowing of the tongues of the valves, with irregular thickening and rigidity; atheroma or calcification of the segments; laceration of one or more segments; adhesion of one or more segments to the inner surface of the ventricle; thickened and stiffened or rupture of the *chordæ tendineæ*, and also contraction and hardening of the musculi papillares.

As a result of the regurgitation of the blood into the left auricle, there is dilatation of the auricle, followed by slight hypertrophy.

Symptoms. Insufficiency of the mitral valves soon leads to cardiac hypertrophy, to compensate for the diminished amount of blood sent onward by the ventricular systole. This condition causes quickened and strong pulse with some shortness of breath on severe exertion. When the "compensation ruptures" there occurs pracordial distress, cough, dyspnæa, feeble, soft, rapid, irregular pulse; finally pulmonary congestion, ædematous limbs and general cyanosis, the abdominal cavity filled, liver congested, urine scanty and albuminous, the patient dying "drowned in his own fluid."

Inspection. Cardiac impulse (apex-beat) displaced to the left and downward. In children and youths, bulging of the præcordia and increased cardiac impulse.

Palpation. Displaced cardiac impulse, early stage being forcible and diffused; as compensation fails, impulse feeble or absent.

Percussion. Transverse and vertical cardiac dulness increased.

Auscultation. Systolic blowing or churning murmur, audible in the mitral area, propagated to the apex, left axilla and under the angle of the scapula, either occurring with or taking the place of the first sound of the heart; the second sound being markedly accentuated.

Prognosis. So long as the compensating hypertrophy can be maintained the prognosis is not unfavorable; when dilatation supervenes, however, the patient soon perishes, either from congestion of the lungs or dropsy and exhaustion.

AORTIC REGURGITATION.

Termed also aortic insufficiency, is next in frequency to mitral insufficiency.

Pathological Anatomy. The valves or segments adhere to the walls of the aorta, or a segment is lacerated or may be perforated, or, more commonly, the segments are shrunken, deformed and rigid,

permitting the regurgitation of the blood. These deficiencies in the valves are usually associated with more or less narrowing of the orifices.

The inability of the aortic valves to close the aortic orifice at the proper moment allows the blood that should go onward to flow back into the left ventricle, and the normal flow of blood from the left auricle continuing, causes overfilling of the ventricle, which results in a dilatation of its cavity, and the extra effort of the ventricle to empty itself results in hypertrophy of the walls. In no other condition does the dilatation and hypertrophy of the cardiac walls reach such a degree. The older writers named this enormous enlargement of the heart cor bovinum.

Symptoms. Those of marked hypertrophy, to wit: forcible cardiac action, headache, tinnitus aurium, congestion of the face and eyes, with *pulsating vessels*, even small ones pulsating that before were not visible to the eye; pulsations of the retinal vessels can be recognized with the ophthalmoscope; the *receding pulse*, which is particularly characteristic—forcible impulse but rapidly declining, called "water-hammer" pulse; also, the "Corrigan pulse."

When "compensation ruptures," dyspnœa, cough, cyanosis, hepatic enlargement, congestion of the kidneys, with scanty, albuminous urine, ascites and dropsy. If mitral insufficiency is now superadded, general venous stasis and death rapidly occur.

Præcordial pain is usually present in aortic disease. It may be a sensation of constriction in the cardiac region, or sharp, shooting pains extending to the arms—anginoidal attacks.

Inspection. Forcible cardiac impulse.

Palpation. Strong, full cardiac impulse.

Percussion. Cardiac dulness increasing transversely and vertically.

Auscultation. First sound, forcible; second sound, replaced or associated with a churning, rushing or blowing murmur of low pitch, distinct at the second right costal cartilage, but most distinct at the junction of the sternum and the fourth left costal cartilage, transmitted downward toward and below the apex.

Prognosis. The one valvular disease most likely to occasion sudden death; still, so long as the compensating hypertrophy remains intact, compatible with quite an active life.

TRICUSPID REGURGITATION.

Pathological Anatomy. This form of valvular insufficiency is either associated with right-sided cardiac dilatation from pulmonary obstruction, or is the result of mitral disease.

The tricuspid orifice is dilated in the majority of cases; occasionally the segments of the valves are contracted or adherent to the ventricle.

Symptoms. Venous stasis with its various consequences, and especially *pulsation of the jugulars*, synchronous with the cardiac movement, and, finally, general venous pulsation, especially of the liver, pulmonary congestion, engorgement of the kidneys, and dropsy. These symptoms are superadded to those of the affections with which tricuspid insufficiency is always associated.

Inspection. Diffused, wavy, cardiac impulse; jugular pulsation synchronous with the cardiac movement, uninfluenced by respiration, also more or less prominent hepatic pulsation.

Palpation. The cardiac impulse extended, but feeble.

Percussion. Dulness on percussion, extending to the right and below the sternum.

Auscultation. The first sound is accompanied by a blowing murmur most intense at the junction of the fourth and fifth ribs with the sternum, distinct over the xiphoid appendix, becoming feeble or lost in the left axillary region; often associated, however, with a mitral systolic murmur.

PULMONIC REGURGITATION.

Pathological Anatomy. Insufficiency of the pulmonary valves is of rare occurrence, but when present the changes correspond more or less with those described for aortic regurgitation.

Symptoms. Those of dilatation of the right side of the heart and consequent pulmonary congestion, to wit: dyspnœa, deficient aeration of the blood and cyanosis, distention of the superficial vessels, palpitation of the heart, præcordial distress, sudden suffocative attacks, and dropsy.

Percussion. The cardiac dulness extending to the right of the sternum.

Auscultation. A loud, blowing murmur associated with the second sound of the heart, most distinct at the junction of the third left costal cartilage and the sternum.

Prognosis. Death results, sooner or later, from dropsy and exhaustion.

MITRAL OBSTRUCTION.

Mitral obstruction or stenosis is not as frequent as regurgitation, and is very often associated with the latter.

Pathological Anatomy. Mitral stenosis is caused by deposits around the orifice, the result of endocarditis, or else the segments of the valves are "glued together by their margins," leaving but a funnel-shaped opening, the so called "button-hole" mitral valve. Vegetations on the valves lead to more or less obstruction to the blood-current.

Symptoms. Hypertrophy of the left auricle results from obstruction at the mitral orifice, followed in time by dilatation, the symptoms of stenosis being unobservable until the "compensation ruptures," or until dilatation becomes excessive, when occur *irregular*, small, and *feeble pulse*, *dyspnwa*, *cough*, bronchorrhœa the result of bronchial congestion; dilatation of the right side of the heart, soon leading to general venous stasis, dropsy, and death.

Inspection. Normal until auricular hypertrophy, when an undulatory impulse is observed over the left auricle.

Palpation. When cardiac dilatation occurs, a diffused, feeble, and irregular cardiac impulse is felt near the xiphoid appendix.

Auscultation. First sound normal in character but often irregular in rhythm. The second sound normal. A blowing, sometimes rasping, sound is heard, immediately after the second sound of the heart ceases, and immediately before the first sound begins—a presystolic murmur, heard most distinctly in the mitral area, lessening in intensity toward the cardiac base. The cardiac sounds are all more or less enfeebled if cardiac dilatation occur.

Prognosis. The prognosis is controlled by the duration of the hypertrophy. Under favorable circumstances mitral stenosis is compatible with a long and rather active life.

AORTIC OBSTRUCTION.

Pathological Anatomy. Stenosis of the aortic orifice is caused by the projection of the valves inward, and their becoming rigid and thickened, or atheromatous or calcareous, so that they cannot be pressed back by the blood, but remain constantly in the current of the circulation. Occasionally the valves are covered with fibrinous

masses, the opening into the artery being thus more or less completely closed, or the segments may be adherent by their lateral surfaces, leaving a central opening, which may be so contracted as to permit the passage of only the smallest probe.

Symptoms. Hypertrophy of the left ventricle rapidly supervenes upon aortic stenosis. The *pulse* is *small*, slow, and hard. The supply of blood to the brain is insufficient in many cases, and hence attacks of *vertigo*, *syncope*, or slight epileptiform seizures occur; finally, dilatation of the left ventricle and incompetence of the mitral valve result, with subsequent pulmonary congestion, dyspnæa, and general venous stasis, the pulse soft and feeble.

Palpation. Lowered cardiac impulse, strong in the early stage, feeble when dilatation occurs.

Percussion. The cardiac dulness is increased vertically, the transverse dulness being slightly affected.

Auscultation. The first sound replaced or associated with a harsh, rasping sound, whistling at times, having its greatest intensity at the junction of the second right costal cartilage with the sternum, transmitted along the vessels; the murmur may sometimes be heard a short distance from the patient.

Usually aortic stenosis is associated with more or less aortic regurgitation, whence a *double murmur occurs*, having its greatest intensity at the base of the heart, the so-called to-and-fro or see-saw murmur.

Prognosis. So long as compensation is maintained the condition of the patient is comfortable, if a quiet life be followed. When the compensation is ruptured, the usual symptoms of dilatation, venous stasis and dropsy, soon ensue.

TRICUSPID OBSTRUCTION.

This condition is one of the rarest affections of the heart, and if it ever does occur with or following an attack of endocarditis, the anatomical changes are similar to those of mitral obstruction. This condition soon leads to auricular dilatation; venous stasis rapidly supervenes, associated with venous pulsations similar to those described when speaking of tricuspid regurgitation.

PULMONIC OBSTRUCTION.

Pathological Anatomy. Always a congenital malady, the changes consisting in "constriction of the pulmonary artery, un-

closed foramen ovale, unclosed ductus Botalli, stricture at the ductus Botalli, with hypertrophy of the right cavity and frequent association with tuberculosis of the lungs."

Hypertrophy of the right ventricle may ensue, the walls becoming almost as thick as those upon the left side.

Those in whom these congenital defects in the cardiac structure occur are otherwise weak, develop slowly, have flabby tissues, soft bones, and seem poorly nourished.

Symptoms. The hypertrophy which often ensues may keep life apparently comfortable for some time, but sooner or later "compensation ruptures," when cough, dyspnoa, cyanosis, and death occur.

Prognosis. The duration of these congenital affections is short, usually from a few days to a few months; although several well authenticated cases record a much longer duration.

DIAGNOSIS OF VALVULAR DISEASES.

In making a differential diagnosis between the various forms of valvular disease of the heart, strict attention must be paid to the points of greatest intensity at which the several murmurs are heard.

A murmur occurring with or taking the place of the first sound of the heart—the ventricular systole—heard most distinctly at the apex, transmitted to the left axilla, and to the inferior angle of the scapula, signifies mitral regurgitation—a mitral systolic murmur.

A murmur occurring with or taking the place of the first sound of the heart, with its point of greatest intensity at the xiphoid appendix, signifies regurgitation at the tricuspid orifice—tricuspid systolic murmur.

A nurmur heard with the first sound of the heart, high-pitched, rasping or grating in character, with its point of intensity greatest at the second right costal cartilage, signifies obstruction at the aortic orifice—an aortic systolic murmur.

A murmur heard with the first sound of the heart, soft in character, with its point of intensity most distinct at the junction of the third left costal cartilage with the sternum, signifies obstruction at the pulmonic orifice—a pulmonic systolic murmur.

A nurmur occurring immediately after the second sound of the heart, and immediately before the beginning of the first sound of the heart, signifies obstruction at the mitral orifice—a presystolic mitral maximum.

A murmur heard with or taking the place of the second sound of the heart, most distinct at the second costal cartilage, to the right of the sternum, and well transmitted toward the apex or below, signifies insufficiency or regurgitation at the aortic orifice—an aortic regurgitant or diastolic murmur.

Although eight distinct valvular murmurs have been described as occurring in the heart, those on the right side are of rare occurrence, and hence of little clinical importance.

If a murmur be heard with the first sound of the heart, it is almost certainly aortic obstructive or mitral regurgitant; and if heard with the second sound, it is probably aortic regurgitant. A presystolic mitral murmur is also of comparatively rare occurrence, the force with which the blood passes from the left auricle into the left ventricle being, under ordinary circumstances, insufficient to excite sonorous vibrations.

Functional or anamic murmurs may be confounded with the various forms of valvular disease of the heart. The chief points of distinction between them are, that an anamic murmur, which is always heard at the base of the heart, is always systolic in time, not transmitted away from the heart, and is soft in character, low in pitch, and of variable intensity, now being heard, now entirely absent.

Treatment. There is no special plan of treatment for each form of valvular disease. Prof. Da Costa says: "I hold that the precise valve affected is not, with our present resources, the keynote to the treatment of valvular heart disease. We are to take as indications:

1. The state of the heart-muscle and of the cavities. 2. The rhythm of the heart-action. 3. The condition of the arteries and veins and of the capillary system. 4. The probable length of existence of the malady and its likely cause. 5. The general health. 6. The secondary results of the cardiac affection."

The important point to bear in mind in the treatment of valvular disease of the heart is that it is associated either with cardiac hypertrophy or dilatation, and the treatment, if any at all be required, is directed toward this secondary condition. If compensation be complete, attention to the condition of the bowels, kidneys, and digestion, with some general directions as to exercise, is all that is required.

If the hypertrophy become marked and excessive, it is best controlled by either aconitum, veratrum viride, or spiritus glonoini.

If dilatation have occurred, the heart weak and feeble, the circula-

tion impeded, and venous stasis has followed, digitalis, caffeinæ citras, strophanthus, or sparteinæ sulphas, with more or less active purgation, is indicated.

If fatty degeneration of the heart result, the indications are for cardiac rest, strychninæ sulphas, stimulants, strophanthus, and attention to the excretions.

If the cardiac rhythm is disturbed, add belladonna to whatever other plan of treatment is being used.

If the capillary circulation is weak, strophanthus and nitro-glycerin (glonoinum) act better than digitalis, which latter has the power of contracting the arterioles.

Any of the secondary results of the valvular affection are to be treated according to the particular indications.

CARDIAC HYPERTROPHY.

Definition. An overgrowth or increase in the muscular tissue which forms the walls of the heart; characterized by forcible impulse, over-fulness of the arteries, diminished blood in the veins, and accelerated circulation.

Causes. Obstruction to the outflow of blood, resulting from valvular disease of the heart; emphysema; Bright's disease; arteriofibrosis; functional over-action; excessive use of tobacco, tea, coffee, or excessive muscular action.

Varieties. I. Simple hypertrophy, or a simple increase in the thickness of the cardiac walls; II. Eccentric hypertrophy, increase in the cardiac walls and dilatation of the cavities, to wit: Dilated hypertrophy; III. Concentric hypertrophy, increase in the cardiac walls with decrease of the cavities, a very rare form.

Pathological Anatomy. Hypertrophy of the heart is usually limited to the left side, the ventricles more commonly than the auricles, the latter dilating.

The shape of the heart is altered by hypertrophy; if the right ventricle, the heart is widened transversely and the apex blunted; if the left ventricle, the heart is elongated and, as a rule, the cavity is dilated; if both ventricles are hypertrophied, the heart has a globular shape. From increase in weight the heart may sink lower during the recumbent position, thereby lessening the area of cardiac dulness, but during the sitting or upright posture it sinks lower in the chest and to the left, causing more or less prominence of the abdomen.

The increase in the size of the organ is a true increase or hypertrophy of the muscular tissue, and not a hyperplasia. The tissue is firmer and the color brighter and fresher than when the size of the organ is normal.

The cor bovinum of the old writers is an enormous hypertrophy of the heart with dilatation of its cavities.

Symptoms. Depend upon the amount of hypertrophy. The most common are increased and forcible cardiac action, the arteries becoming fuller, the veins less full and the circulation accelerated, pulsating carotids and aorta, headache, often vertigo, frequent epistaxis, congestion of the face and eyes, tinnitus aurium, dyspnwa on exertion, dry cough, restless nights, with more or less jerking of the limbs, occasional præcordial pains shooting toward the left axilla, full, firm, bounding pulse, and pulsations in the superficial arteries.

A sphygmographic tracing shows the line of ascent vertical and abrupt, but the apex is rounded, and the line of descent is oblique, unless there is more or less insufficiency of the valves.

Inspection. Often fulness or prominence of the præcordium, with distinct impulse.

Palpation. The impulse is felt one or two intercostal spaces lower down and to the left, and is stronger and more or less diffused—the heaving impulse.

Percussion. The area of cardiac dulness is increased vertically and transversely upon the left side of the sternum, unless the right ventricle is also hypertrophied, when the cardiac dulness is increased to the right of the sternum.

Auscultation. If simple hypertrophy without any coexisting changes in the valves or orifices, the first sound has a loud and somewhat metallic quality, the second sound being strongly accentuated.

Sequelæ. Cerebral hemorrhage; miliary cerebral aneurisms; dilatation of the heart; fatty changes in the cardiac tissue.

Diagnosis. Hypertrophy of the heart can scarcely be mistaken for any other disease if a careful study of the physical signs be made.

Prognosis. When the result of valvular disease, the hypertrophy is said to be compensatory. If the result of Bright's disease, emphysema of the lung, or if occurring late in life, or associated with atheromatous degeneration of the vessels, the prognosis is unfavorable; when the result of functional over-action in the strong and robust, a

further enlargement can often be prevented by active and persistent treatment.

Treatment. The indications are, if the hypertrophy be excessive, to *lessen the force* and *number* of the cardiac pulsations and to remove the cause whenever possible.

The former indications are best met by the persistent use of tinctura aconiti in small doses, gtt. j-ij, three times a day, or tinctura veratri viridis, gtt. j-ij, three times a day, at the same time keeping the bowels, kidneys, and the skin acting freely. A certain amount of hypertrophy is beneficial in chronic valvular disease, and drugs should not be administered simply because a cardiac murmur is discovered on auscultation.

The habits of the patient are to be corrected, all laborious or active exercise to be restricted, the patient to be in the recumbent posture several hours during the day if possible, the diet being restricted, avoiding all forms of stimulants, such as liquors, tobacco, tea, and coffee.

Cases of cardiac hypertrophy associated with Bright's disease are relieved by *digitalis*, the cardiac distress being secondary to the kidney disease, for which the digitalis is used.

Cases of cardiac hypertrophy associated with anæmia should, in addition to *digitalis* and rest, be placed upon a course of *ferrum*.

DILATATION OF THE HEART.

Definition. An increase in the size of one or more of the cavities of the heart, without any increase or thickening of the cardiac walls; in fact, the walls are frequently thinner—stretched; characterized by feebleness of the circulation, terminating in venous stasis, cyanosis, cedema, and exhaustion.

Causes. Over-exertion in those of feeble resisting powers, as youths or soldiers, as first pointed out by Prof. Da Costa; chronic valvular disease; emphysema; chronic bronchitis; gout; Bright's disease; alcoholism; syphilis.

Varieties. I. Simple dilatation, the cavities being enlarged, the walls normal. II. Active dilatation, corresponding to eccentric hypertrophy; the cavities being enlarged and the walls increased in thickness, the so-called "dilated hypertrophy." III. Passive dilatation, the cavities being enlarged and the walls thinned or stretched.

Pathological Anatomy. The right side of the heart is far more frequently involved than the left side. The shape of the organ is altered, depending on the part affected. The weight of the organ is, as a rule, increased, as hypertrophy almost always accompanies or precedes dilatation.

The muscular tissue is generally pale, mottled, and softened, and under the microscope presents evidences of degeneration. The orifices also participate, and especially the auriculo-ventricular, resulting in the valves becoming incompetent to close the orifices, and this latter effect is added to by the removal of the basis of the papillary muscles a greater distance from the orifice, in consequence of the extension of the wall.

When the auricles dilate, the large venous trunks opening into them unprotected by valves commonly participate in the dilatation, and may become greatly enlarged.

The passive congestion of the organs that follows the feeble circulation produces changes in their structure.

Symptoms. Those associated with enfeebled circulation, to wit: feeble pulse, veins distended, arteries emptied; headache, aggravated by the upright position; attacks of syncope, cough, with any of the following phenomena of venous congestion: of the lungs, dyspnwa; liver, jaundice; stomach, dyspepsia; intestines, constipation; kidneys, scanty often albuminous urine; brain, dulness of the mind and vertigo, often relieved by a copious epistaxis; and, finally, dropsy, beginning in the lower extremities, the patient dying from exhaustion.

Great relief often temporarily follows any of the above symptoms under treatment; sooner or later, however, the venous stasis produces the final symptoms noted.

Inspection. Veins of the surface distended and enlarged; indistinct cardiac impulse, often diffused and wavy; if associated with tricuspid insufficiency, there is pulsation of the jugular.

Palpation. Feeble and irregular fluttering but heaving impulse.

Percussion. Cardiac dulness extended transversely, and especially increased on the right side.

Auscultation. If no valvular lesion accompany the dilatation, the cardiac sounds are weaker than normal, the first sounds having a sharper quality than normal; if accompanied by valvular lesions, cardiac murmurs are present.

Diagnosis. Hypertrophy of the heart shows increased cardiac

dulness, and is a disease of powerful cardiac action, while dilatation is an affection of feeble action associated with dropsy.

Pericardial effusion has many points of resemblance to cardiac dilatation, but it begins suddenly, associated with some acute malady; and while the heart sounds are indistinct or feeble at the apex, they both have their normal qualities at the cardiac base, while dilatation of the heart has a chronic history, results in general venous stasis, the cardiac sounds being of the same intensity over the entire præcordia.

Prognosis. Unfavorable, death resulting from gradual exhaustion, or suddenly by cardiac paralysis if there be some undue excitement.

Treatment. Dilatation of the heart is incurable. Palliative measures are of but temporary benefit. In all cases there are two important indications to be met, the first to maintain the general nutrition of the patient, and the second to control or prevent all irregular or violent cardiac action. The first indication is accomplished by a generous diet, moderate exercise, with bitters to increase the appetite and ferrum to improve the blood, and, in a majority of cases, the more or less free use of a good red wine.

The second indication is met by the observance of strict rules in regard to exercise and such heart tonics as *digitalis* in powder, tincture, or infusion, or a combination like the following:—

Strychninæ sulphas, gr. 24, three times daily, is a valuable cardiac tonic; the same may be said of caffeinæ citras, gr. j-iij, three or four times daily. Sparteinæ sulphas is a powerful cardiac tonic, particularly of service in the dilating heart of Bright's disease. The tinctura strophanthi, alone or in combination with digitalis, is valuable. Ext. convallariæ, fld., is not always reliable. Morphinæ sulphas in small doses, particularly when compensation is failing and the dropsy becomes great, and is associated with marked cyanosis, hypodermically, as suggested by Prof. Bartholow, "often acts like magic in restoring the circulation."

The following pill is often of great advantage:-

R.	Ferri reduct.,	۰	۰	٠	٠	9	٠	۰					gr. j-ij	
	Quininæ sulph., .			٠		٠	٠		٠				gr. j–ij	
	Pulv. digitalis, .												gr. i	
	Morphinæ sulph.,			٠	٠			0		۰	٠	۰	gr. $\frac{1}{24}$.	M.
	-Three times a da													

An excellent combination is the following:-

R.	Tinct. digitalis, f z jss	
	Tinct. cacti grandiflor., f 3j	
	Caffeinæ citratis,	
	Tinct. card. comp ad $f \stackrel{\approx}{\mathbf{z}} iv$.	M.
Cro	Teconomial diluted three or four times delly	

SIG.—Teaspoonful, diluted, three or four times daily

The bowels, skin, and kidneys should be kept in action, using, if needed, purgatives, diaphoretics, and diuretics.

If pulmonary congestion develop, dry cups, digitalis, caffeina, and stimulants.

For cardiac asthma, dry cups, morphinæ sulphas, hypodermically, or spts. ætheris compositus (Hoffman's Anodyne).

For hepatic congestion, blue mass or podophyllin.

For dropsy, dry cups over the kidney, digitalis or potassii acetas, with scoparius and juniperus, and pulv. jalapæ comp., 3j-ij, in water, before breakfast.

If the dropsy is uninfluenced by the above means, success will follow the use of *hydrargyri chloridi mitis*, gr. iij, guarded with *pulv. opii*, gr. $\frac{1}{12}$, three or four times a day, as I have frequently witnessed.

ACUTE MYOCARDITIS.

Synonyms. Carditis; abscess of the heart.

Definition. An inflammation of the muscular tissue of the heart, by extension from an inflamed pericardium or endocardium, or secondary to pyæmia; characterized by pain, feeble circulation, symptoms of blood poisoning, and collapse.

Causes. The result of endocarditis or pericarditis; pyæmia; typhoid fever; emboli of the coronary arteries.

Pathological Anatomy. Discoloration and softening of the cardiac substance and the infiltration of a sero-sanguineous fluid, fibrinous exudation and pus, leading to the formation of abscesses in the muscular structure of the heart.

The disease leads to the formation of either a cardiac aneurism or to rupture of the walls of the heart. If recovery occur, cicatrices or depressed scars may mark the site of a former abscess.

Symptoms. The clinical evidences of inflammation of the cardiac muscle are very obscure. If, during the course of one of the maladies mentioned, there are developed *pracordial pain*, irregular

and feeble cardiac action, cardiac dyspnæa, pyrexia of a low type, with symptoms of blood poisoning, and a tendency to collapse, or the symptoms of the so-called typhoid state, myocarditis may be suspected.

Diagnosis. The existence of myocarditis can scarcely ever be anything but a presumption, the signs being all negative rather than positive. If during the course of rheumatism, pyæmia, puerperal fever, typhoid fever, pericarditis, or endocarditis, symptoms of cardiac failure appear suddenly, associated with signs of blood poisoning and collapse, inflammation of the cardiac muscle may be suspected.

Prognosis. The course of acute myocarditis is very rapid, death being the usual termination, in from three to five days. Chronic myocarditis pursues a very latent course.

Treatment. Largely symptomatic. Perfect rest of mind, generous diet, free stimulation and the administration of quinina, ferrum, spiritus ætheris nitrosi—a nitrite.

CHRONIC MYOCARDITIS.

Synonyms. Fibroid heart; chronic interstitial myocarditis; fibrous myocarditis; chronic carditis; cardio-sclerosis.

Definition. A slowly developing hyperplasia of the interstitial connective tissue of the heart, leading to induration of its substance; characterized by shortness of breath on slight exertion, attacks of tachycardia, præcordial pain, disordered circulation, and vertigo. It is proper to state that many cases present no symptoms whatever.

Causes. The most frequent cause is sclerosis of the coronary arteries, leading to imperfect blood supply to the cardiac muscles. Amongst other frequent causes are diseases of the kidneys, alcoholism, excessive use of tobacco, syphilis, secondary to pericarditis, endocarditis, and acute myocarditis.

There is, undoubtedly, often an inherited predisposition to fibroid changes in the vessels, in which cases the causes named would act as exciting causes.

It is a disease of the aged, save in those instances resulting from excesses. The old saying, "A man is as old as his arteries," is applicable to this disease.

Pathological Anatomy. The heart is enlarged and dilated. The morbid changes may be diffused, or limited to the walls of the left ventricle, the papillary muscles, and the septum. There is always

more or less atheromatous deposit or changes in the aorta. All cases show atheroma in one, more, or all of the coronary arteries. Complete closure of one coronary artery, if produced suddenly, is usually fatal.

On section the cardiac wall cuts with a distinct resistance. The changes in the heart wall are an "overgrowth of the interfibrillar connective tissue, with development of fibrous tissue. These changes may be uniformly distributed through the substance of the heart when some intoxication, as by alcohol, or some general disturbance of the cardiac nutrition, has led to the myocardial disease; or they may be seen in circumscribed areas when embolic or thrombotic occlusion of branches of the coronary arteries has occasioned anæmic infarction and subsequent sclerosis. In either case the microscope reveals masses of wavy fibrous tissue between the muscular bundles, and often slow degeneration or atrophy of the fibres themselves" (Pepper).

The terminal branches of the coronary arteries are narrowed and sclerotic to the point of obliteration, particularly in cases resulting from syphilis.

"Aneurism of the heart is commonly due to localized cardiosclerosis. The inelastic fibrous tissue gradually gives way before the intracardial pressure, and saccular dilatation results" (Pepper).

Atheromatous changes are often found in other than the coronary vessels, particularly the aorta.

Various degenerative changes occur in other organs, the result of disturbed circulatory action.

Symptoms. The great majority of patients having chronic myocarditis present no symptoms until an extra cardiac effort is called for.

An early symptom is *breathlessness* on slight exertion, with either cardiac *palpitation* or a *feeble*, *irregular pulse*. Anginal attacks (cardiac pain) or a sensation of constriction or pressure over the præcordia are frequent, often following some exertion or an attack of indigestion. The pulse-rate is decreased in number in cases which present no other symptom.

A frequent symptom is *syncope*, coming without warning or after sudden exertion, the result of sudden failure of the cerebral circulation.

Amongst other periodical symptoms are cardiac asthma, pseudo-apoplectic attacks, hepatic, gastric, and nephritic disorders.

As the fibroid changes progress, there develops progressive weak-

ness, dyspnœa, insomnia, disordered digestion, and cerebral weakness, often showing itself as mania, delusional attacks, or dementia.

Percussion. Increased præcordial dulness is usually present, due to the dilated hypertrophy.

Auscultation. The first sound of the heart is valvular in character, the booming or muscular quality having disappeared. Murmurs are very frequent, the result of valvular disease. A very characteristic point is the irregularity in rhythm and in force, one contraction being fairly forcible, another weak or feeble, and so on.

Diagnosis. A proper appreciation of chronic myocarditis is one of the most important questions in clinical medicine. The term *Heart Failure* is the opprobrium of the profession, and yet chronic myocarditis is one of the great causes of cardiac failure during the prevalence of some over-exertion, in acute pneumonia, typhoid fever, and other like diseases.

The points of value in arriving at a diagnosis are: a careful study of the first sound of the heart at the apex; the character of murmurs if present, the condition of the arteries, the dyspnœa, the feeble, irregular pulse in patients past fifty years, and the occurrence of anginal attacks after exertion or mental worry.

Prognosis. This is controlled by the habits of the patient. The disease is incurable, but life may be fairly comfortable for many years if care be exercised.

Treatment. No remedy can remove the fibroid change. The indications are to promote the patient's nutrition, hold in check the progress of the disease, and meet or prevent the symptoms as they arise.

For the general condition, ferrum, arsenicum, and the hypophosphites.

For the breathlessness, spiritus glonoini (nitroglycerin, one per cent.), or spiritus ætheris nitrosi, or spiritus ammoniæ aromaticus.

For cardiac palpitation, potassii bromidum, or spiritus ammoniæ aromaticus.

For cardiac weakness, hypodermic injections of strychninæ sulphas, gr. $\frac{1}{24}$, three or four times a day, and if the pulse is frequent, tinctura digitalis, m x-xx by mouth, three times daily; maintaining the recumbent position and removing all unfavorable associate symptoms, as constipation, scanty urine, and dyspepsia with flatulence.

For the anginal attacks, hypodermic injections of morphine sulphas, gr. 1/8-1/4, or chlorodyne, M. x-xx, repeated as needed.

For the *syncopal attacks*, the patient placed in bed and stimulants administered, often used by the hypodermic method.

The patient must lead a quiet life, refrain from mental worry, physical over-exertion, and eschew *tobacco* and malt liquors. The diet must be plain and simple with but little tea or coffee. In the elderly, a small amount of good whisky once or twice a day is valuable.

FATTY HEART.

Synonyms. Fatty degeneration of the heart; chronic myo-

Definition. A change in the muscular fibres of the heart, in which the transverse striæ are replaced by granules and globules of fat; characterized by feeble cardiac action, venous stasis, and dyspnæa.

Causes. Impaired nutrition in the elderly; prolonged anæmia; chronic gout; alcoholism; phosphorus poisoning; cancer; tuberculosis and scrofula; diseases of the coronary arteries.

Pathological Anatomy. The distinction must be made between a deposit of fatty tissue upon or around the heart, and the degeneration of its muscular tissue.

The fatty metamorphosis may affect the whole organ, or the entire ventricular walls, or be limited to portions of them. If the degeneration be marked, the color is yellowish, the tissues soft and easily torn, and to the touch have a greasy feeling, oil being yielded on pressure.

The microscopic changes are characteristic. The striæ of the muscle are early rendered indistinct by fat and oil globules, gradually becoming more and more obscured, and finally disappearing altogether, the fibres being replaced by fat granules.

Symptoms. Those of weak heart, anæmia of organs, and venous stasis, to wit: feeble, irregular, but slow cardiac action, compressible pulse, pracordial distress, often aggravated by attacks of angina pectoris; dyspnæa, aggravated on exertion, with anæmia of the various organs from the feeble propulsive power; if of brain, vertigo, swooning, or pseudo-epileptic attacks, especially marked on suddenly rising from a recumbent position; if of lungs, dry, hacking cough; if of gastro-intestinal tract, dyspepsia and constipation; if of kidneys,

scanty urine, at times albuminous; and finally dropsy, beginning in

A formidable symptom, causing much inconvenience as well as alarm to the patient, is what he will term his constant "sighing," the Cheyne-Stokes breathing—"A pause in the breathing, a complete suspension of the respiratory acts for a period of time (during which breathing might occur several times in the normal manner), then the resumption of respiration very feebly and slowly, and a gradual and progressive increase in the number and depth of respirations until the maximum is reached, and then again a gradual and progressive diminution, in the same order, in the number and depth of the respirations, until another pause occurs"—the "oscillating respiration."

Concomitant symptoms are atheromatous change in the vessels, and the arcus senilis.

Palpation. Weak cardiac impulse.

Percussion. Not markedly changed unless preceded by enlargement of the heart.

Auscultation. First sound feeble, toneless, almost inaudible, the second sound being normal, unless changes in the valves are present.

Diagnosis. Feeble cardiac sounds, with slow pulse, attacks of cardiac asthma or Cheyne-Stokes breathing, with evidences of arcus senilis, make the diagnosis very certain. The question of fibroid heart must always be considered.

Prognosis. Incurable, the affection pursuing a more or less chronic course. Life may be prolonged at times by treatment, but death finally results from exhaustion, or suddenly, from cardiac paralysis or rupture of the heart.

Treatment. Incurable, there being no plan of treatment that can restore the degenerated muscular fibre. Generous diet, very moderate exercise, stimulants, oleum morrhuæ, and the "triple elixirs,"—elixir ferri, quininæ et strychninæ.

All the excreting organs must be kept active, so as to relieve the crippled heart as much as possible.

To sustain the cardiac action, strychninæ sulphas, gr. $\frac{1}{36}$ $\frac{1}{48}$, three or four times daily is most valuable. Other drugs are caffeinæ citras, sparteinæ sulphas, or tinctura nucis vomicæ. Digitalis is contra-indicated in advanced cases.

For syncopal attacks, spiritus ætheris nitrosi, spiritus ammoniæ

aromaticus, or hypodermic injections of ætheris, camphora, or spiritus frumenti.

The recumbent position for hours each day is valuable.

PALPITATION OF THE HEART.

Synonym. Irritable heart.

Definition. A functional disturbance of the heart; characterized by increasing frequency of its movements and more or less irregularity of the rhythm, with a strong tendency toward hypertrophy.

Causes. Over-exertion, "the heart strain" of Da Costa; dyspepsia; uterine diseases; excesses in tea, coffee, tobacco, alcohol, or venery; moral and emotional causes, grief, anxiety, and fear.

Symptoms. Usually palpitation of the heart has a sudden onset after some one of the causes mentioned, pracordial oppression or pain, rapid, tumultuous beating, the impulse being visible through the patient's clothing, dyspnæa, anxiety, and a sense of choking or fulness in the throat, the recumbent position impossible, vertigo, faintness, flashes of light, the pulse full and strong or feeble, the face flushed or pale, the patient having a feeling of anxiety with a sense of impending danger and a fear of sudden death. These attacks are paroxysmal, lasting from a few moments to several hours, or a day, the patient often voiding a large quantity of limpid urine after the paroxysm has subsided, when there is a strong tendency to sleep.

Diagnosis. Irritability of the heart is differentiated from the various forms of cardiac disease by the absence of all the physical signs mentioned as occurring in those conditions.

Prognosis. If early and properly treated, favorable.

Treatment. The first point in the treatment of irritability of the heart is to remove the cause; the next, to prevent the recurrence of the attacks of palpitation.

The majority of cases do well by a combination of digitalis and belladonna. Permanent relief is often afforded by a combination of potassii bromidum and veratrum viride. Trional, gr. x-xv, three times daily, is often useful. If the patient be anæmic, excellent results follow the prolonged use of the elixir ferri, quininæ et strychninæ. Locally, emplastrum belladonnæ to the præcordium affords relief. The acute attack is often wonderfully benefited with ice over the præcordium.

TACHYCARDIA.

Synonyms. Rapid heart; quick heart; paroxysmal rapid heart. Definition. Paroxysmal rapid cardiac action minus or with subjective symptoms, the result of excessive cardiac rapidity.

Causes. Tachycardia is one of the "crises" of cerebral or spinal diseases. Menopause. Neuritis of the pneumogastric nerve; chronic myocarditis; neurasthenia; chronic gastritis; excessive use of tobacco.

Pathological Anatomy. No characteristic lesions. There may be paralysis of the inhibitory fibres of the vagus, an irritation of the accelerators of the sympathetic, or to reflex action from some lesion in the cardiac-wall or elsewhere.

Symptoms. The paroxysm is *sudden* in its onset, with or without "warnings"—if these latter, they are in the shape of vertigo, ringing in the ears, and a sense of impending danger. The cardiac action is increased to 150, 175, 200, rarely 250 beats per minute. The pulse is small, weak, easily compressible, and often irregular. The respiration is slightly increased; rarely there is dyspnæa. The surface is at first pale, but soon becomes flushed. The expression is anxious and denotes suffering. There is a feeling of præcordial constriction with more or less smothering. Rarely, there are no subjective symptoms.

The duration is from a few minutes, to hours, or days.

Auscultation. The first sound is clear and ringing, but not strong and booming. The second sound is weak and lacks the valvular quality of the normal. A murmur is often heard at the apex.

Diagnosis. The differentiation between tachycardia and palpitation is to be made, as also the rapid heart of valvular disease and of irritable heart. The chief point is that in tachycardia the attack is paroxysmal, and the number of pulsations exceeds the rapid heart of other conditions.

Prognosis. As a rule, it is an unfavorable symptom of some central lesion. If it develops in patients suffering from chronic myocarditis or atheroma of vessels, the fatal result may be sudden.

Treatment. For the paroxysm the application of ice to the precordia, conjoined with a hypodermic injection of morphinæ sulphas, gr. $\frac{1}{100}$, and atropinæ sulphas, gr. $\frac{1}{100}$, and rest in bed. Tinctura belladonnæ, potassii bromidum, lithii bromidum, strontii bromidum, or camphoræ monobromas are often valuable, what answers in one

case or attack being useless in another. Trional, gr. xxx, seems to rapidly control a paroxysm.

After the paroxysm, nutritious diet, avoidance of alcohol, tobacco, tea, and coffee, and a course of arsenicum, strychninæ, or potassii iodidum.

BRADYCARDIA.

Synonym. Brachycardia.

Definition. A paroxysmal or permanent slowness in the cardiac action.

Causes. Often associated with organic nervous diseases. It is a symptom of such cardiac diseases as fibroid and fatty heart and atheroma of the coronary arteries.

It frequently occurs during convalescence from infectious diseases, such as diphtheria, pneumonia, typhoid fever, erysipelas, and rheumatism; uræmia, lead poisoning, anæmia, and chronic alcoholism are often causes.

Symptoms. Slow action of the heart is the chief symptom, varying from 50, 40, 30, 20, to 10 or 8 beats per minute. The pulse is weak, small, and slow. As results of the slow cardiac action are vertigo, noises in the ears, syncopal attacks, and rarely convulsions. The onset may be either sudden or follow "warnings."

Auscultation. The first sound is soft and feeble, and often the second sound is not heard.

As a rule, with reduction in the number of contractions is an increase in their force; this not obtaining in bradycardia determines its central origin.

Diagnosis. A feeble cardiac contraction, with less than fifty beats per minute, determines the diagnosis.

Prognosis. Sudden death a very frequent termination. The cause controls the prognosis.

Treatment. Rest in the recumbent position, heat to the præcordia, and the use of such remedies as atropinæ sulphas, caffeinæ citras, strychninæ sulphas, spiritus glonoini, or spiritus ammoniæ aromaticus. Often the emergency is so great as to call for the hypodermic use of the selected drug.

Digitalis is contra-indicated. Between the paroxysms, such remedies as improve the general health and prevent the progress of the central or exciting cause.

ARRHYTHMIA.

Synonyms. Arrhythmia cordis; irregularity of the pulse.

Definition. A lack of cardiac rhythm, or irregularity in the cardiac pulsations. It is a symptom rather than a disease.

Causes. Valvular diseases; myocardial diseases; cardiac dilated hypertrophy; atheroma of coronary arteries and aorta; excessive use of tobacco, tea, coffee; flatulent dyspepsia. Neurasthenia, hysteria, and melancholia.

Symptoms. An irregularity in cardiac action, either in the rhythm or the regularity in the *force* of the beats, or an intermission in the cardiac contractions

The sphygmograph gives the exact condition of the cardiac pulsations and should always be used in cardiac diseases.

Other symptoms that may be present are due to the condition producing the arrhythmia.

Diagnosis. An examination of the pulse, auscultation of the heart, and the use of the sphygmograph determine the arrhythmia.

Prognosis. Depends upon the cause. In functional cases favorable, in organic cases unfavorable.

Treatment. Rest of mind and body, regulated diet, and attention to the secretions.

Tinctura nucis vomicæ, strychninæ sulphas, and digitalis are each useful. In functional cases the bromides are valuable.

ANGINA PECTORIS.

Synonym. Neuralgia of the heart.

Definition. Paroxysms in which there occur sharp cardiac pains, extending usually into the left shoulder and down the left arm, accompanied by a feeling of constriction of the thorax and a strong fear of impending death.

Causes. Depending upon the variety, whether of nervous or organic origin. Often hereditary; associated with chronic cardiac changes, as diseases of the coronary arteries or calcification of the valves; the excessive use of tobacco; syphilis; according to Trousseau, it is a form of masked epilepsy, and may alternate with true epileptic attacks; often associated with hysteria.

Pathological Anatomy. A disease of the arteries, ossification

and occasionally obliteration of the cardiac arteries, producing cardiac ischæmia.

"The pathological changes which stand in a causative relation to the attacks are those of the cardiac plexus of the phrenic and of the pneumogastric nerves. Pressure of enlarged lymphatics, inflammation of parts of the cardiac plexus, with changes in the coronary arteries, seem to be most constant."

Symptoms. A paroxysmal affection, the attacks occurring irregularly; in the interval entire absence of symptoms, or the symptoms of the organic disease causing the paroxysm.

"The patient suddenly sits up in his bed; with a cry of horror indicates the sense of pain at the præcordium. This pain is of great intensity, but is of a cold and sickening character; the chest is fixed, the breathing quickened, and the hand placed over the præcordia finds that the heart's action is slight and enfeebled. The face wears a look of horror, pale and slightly leadened; a cold sweat breaks out upon the forehead; worse than the pain is the feeling of fearful sickness and depression. The poor patient gasps, 'I shall die! I shall die!' and sometimes his short but concentrated sufferings in a few moments end in death. The attack ends suddenly with vomiting, or great flow of urine."

The unpleasant sensations of these patients during an attack, and the nervous disorder associated with it, slowly bring about a mental change. They are depressed and gloomy, sometimes suicidal, and often developing epilepsy.

Attacks of angina in nervous women and children, the hysterical or pseudo-anginal attacks, come on gradually with distention of the abdomen, eructations of gas, excessive restlessness, flushed face, irritable pulse, diffused præcordial pain, and general hysterical phenomena.

Diagnosis. The points to be remembered are that the attacks are always paroxysmal, the patient having a sense of coldness, and frequently a cold sweat, the heart's action not increased, the chest fixed, and the breathing slow.

Prognosis. True angina pectoris is unfavorable, the patient, sooner or later, either succumbing during the paroxysm or from exhaustion, the result of the cardiac changes.

Pseudo-angina is always favorable.

Treatment. During the intervals between the attacks, an attempt

should be made to remove the exciting cause or diminish its predisposing influence.

For the organic form, no one remedy is comparable with a long course of *potassii iodidum*, gr. x-xx, three times daily, as the frequency and intensity of the attacks are diminished and a fair number of cases are cured, proving the axiom, "the iodides are the digitalis of the arteries."

For the nervous form, all violent emotions and active physical exercise is to be avoided, the diet regulated, and the excretions watched. Among the drugs that are useful are ferrum, arsenicum, strychnina, phosphorus, and zincum. If the cardiac action be weak, use strophanthus. Trousseau urges the administration of belladonna in continuous small doses, on the ground of the analogy of the affection to epilepsy. Quain states that a continuous current, the positive pole on the sternum and the negative pole on the lower vertebræ, lessens the severity and frequency of the anginal paroxysms.

For the attack, prompt relief follows the use of amyl nitris, mijj, inhaled at the instant, or morphinæ sulphas, gr. $\frac{1}{16}$ - $\frac{1}{14}$, to which may be added with advantage atropinæ sulphas, gr. $\frac{1}{120}$, hypodermically, or nitro-glycerin, gr. $\frac{1}{100}$ - $\frac{1}{75}$ - $\frac{1}{50}$, every three or four or five hours. In many cases the use of gr. $\frac{1}{200}$ of this powerful drug, three or four times a day for a long time, lessens not only the frequency but the severity of the paroxysms. Chlorodyne, m x-xv, repeated, often answers well. Chloroformum has proven prompt, efficient, and harmless administered as suggested by Balfour, viz.: "a half drachm is poured upon a sponge at the bottom of a wide-mouthed bottle, from which the patient may breathe ad libitum." Dr. William Evans recommends sparteinæ sulphas, gr. $\frac{1}{4}$ t. i. d., between attacks to prolong the interval and lessen the severity of the paroxysms.

ARTERIO-SCLEROSIS.

Synonyms. Atheroma; anterio-capillary fibrosis (Gull and Sutton); endarteritis chronica deformans (Virchow).

Definition. An overgrowth of the connective tissue of the arteries followed with calcareous deposits. The changes may extend to the capillaries and veins. As a result of the impairment of the arterial circulation occur fibroid degenerations in other organs, resulting in loss of elasticity in the walls of the vessels, increase of arterial ten-

sion, narrowing of the calibre of smaller arteries, and impairment of the nutrition of the organs supplied.

Causes. Old age, alcoholism, syphilis, lead-poisoning, diabetes, malaria, rheumatism. Heredity is a predisposing factor in some cases. Chronic nephritis. More common in men than in women.

Pathological Anatomy. The atheromatous changes are most frequent in the aorta. Other arteries affected are the coronary, the radial, ulnar, brachial, iliac, femoral, and the arteries of the brain.

The internal surface of the affected vessel is irregularly thickened with either gelatinous and translucent, or dense and fibrous or calcareous, deposits or products. If the calcification is extensive, the vessel is changed into a hard, stiff tube. Often the surface of the thickening or deposit is destroyed, presenting the so-called "Atheromatous ulcers," which may be covered with masses of thrombus.

The above changes are the result of inflammatory change in the intima of the affected vessel. This appears three or four times as thick as normal, due to the swelling of its elements, the new growth of connective tissue, and the deposit of round cells. Fatty degeneration of the inflammatory products results.

The result of the changes in the arteries is a loss of their elasticity, thus hindering the propulsion of the blood current and raising the arterial tension, leading to hypertrophy of the left ventricle. The changes finally affecting the coronary arteries lead to changes in the myocardium. If the intima of the smaller vessels be involved the blood supply to the organs supplied is lessened, resulting in disturbance of their nutrition.

Symptoms. Not always apparent. The symptoms vary with the arteries involved and the organs whose blood supply is lessened or cut off.

Cardiac hypertrophy from the increased resistance to the arterial circulation.

The peripheral arteries involved in the atheromatous changes can be determined by palpation, they having a hard, bony feeling, much like a whip-cord.

Attacks of vertigo, pseudo-apoplectic attacks, or spells of unconsciousness in the aged or those having superficial hardened arteries are generally due to changes in the cerebral vessels. Evidences of myocarditis and angina pectoris point to atheroma of the aorta and cor-

onary arteries. Gangrene of the extremities in the old—senile gangrene—point to atheroma or thrombi, the result of the fibrosis.

Palpation. Hard, superficial arteries, those at the wrist feeling like a string of beads, pulsating. The cardiac impulse is forcible in the early stages.

Percussion. Increased præcordial dulness, particularly over left ventricle

Auscultation. In the early stages the first sound of the heart is prolonged, the second sound accentuated over the aortic cartilage. As the heart dilates and the walls become diseased, the sound becomes feeble and often irregular and intermittent.

Diagnosis. Only determined by a close study of the various symptoms and sequelæ,

Prognosis. Incurable.

Treatment. Entirely symptomatic. No remedy can remove the fibroid changes.

ANEURISM OF THE AORTA.

Varieties. I. Aneurism of the arch of the aorta. II. Aneurism of the thoracic aorta. III. Aneurism of the abdominal aorta.

The arch of the aorta is divided by Gray into three parts, the ascending, the transverse, and the descending.

The ascending portion is two inches in length, arising from the left ventricle, on a level with the lower border of the left third costal cartilage, behind the left edge of the sternum. It ascends obliquely upward to the right to the upper border of the right second costal-sternal articulation. The transverse portion commences at the upper border of the right second sternal articulation, and, arching to the left and forward, passes in front of the trachea and cosophagus to the left of the third dorsal vertebra. The descending portion extends downward to the left side of the fourth dorsal vertebra.

The thoracic aorta extends from the left lower border of the fourth dorsal vertebra, and ends in front of the body of the twelfth dorsal vertebra, at the aortic opening in the diaphragm.

The abdominal aorta begins at the aortic opening in the diaphragm, descends a little to the left side of the vertebral column, and terminates over the body of the fourth lumbar vertebra, where it divides into the two common iliac arteries.

Definition. A circumscribed dilatation of some portion of the aorta, the result of disease of the vessel wall weakening its resistance to the blood pressure.

Causes. Those causing arterio-sclerosis are the chief causes. Exertion is an exciting cause. Aneurisms occur in early middle life rather than in old age, when the force of the heart has decreased. More common in men than in women.

Pathological Anatomy. All aneurisms may be divided into two classes, dissecting and circumscribed.

Dissecting Aneurism—false aneurism—is the result of fatty changes in the internal and middle coats of the artery. The shape may be sacculated, fusiform, or cylindrical. A disease of the aged. Circumscribed Aneurism may be true or false, depending on the rupture of the walls or not. It is a disease of middle life or under. Most frequent in men, usually a true dilatation. Syphilis is a most frequent cause.

ANEURISM OF THE ARCH.

Symptoms. The onset is usually gradual, with evidences of arterio-sclerosis and failing health.

Pain, either paroxysmal or constant, is a constant symptom, with increasing dyspnea. The difficulty in breathing may be constant with exacerbations, or it may be remittent. Rarely dysphagia occurs. A slight cough from pressure on the laryngeal nerve with more or less alterations in the voice may be present. The pupils are dilated or contracted or are irregular, in some cases due to pressure on the sympathetic nerve. There is a gradual loss of flesh, disorders of the circulation, and a careworn expression of the face.

Inspection. Negative until the appearance of a pulsating tumor. Palpation. A pulsation over the tumor expansive in character (Corrigan's Sign).

If the aneurism is situated at the transverse portion of the arch, the left pulse and the left carotid are smaller and weaker than those on the right side. Tracheal tugging is a diagnostic sign (Page). "Place the patient in the erect position with his mouth closed and chin elevated to the fullest extent. Then, on grasping the cricoid cartilage between the fingers and thumb and making gentle traction upward, the pulsations of dilated aorta or aneurism, if any exist, will be distinctly felt, in most cases transmitted through the trachea to the hand."

Percussion. Dulness, the extent depending on the size of the tumor. Dulness, other than cardiac, across the sternum is diagnostic of a mediastinal tumor.

Auscultation. Over the tumor a murmur or bruit is usually heard, synchronous with the first sound of the heart. It is louder than the systole, lower in pitch, and of a blowing character.

Diagnosis. If the tumor can be seen or felt, the diagnosis is made, its location being determined by a study of the physical signs.

ANEURISM OF THE THORACIC AORTA.

Symptoms. The most constant symptom is deep-seated thoracic pain, constant or paroxysmal. Dysphagia is a frequent condition. There is seldom dyspnæa, and alteration of voice and pupils does not occur.

Physical Signs are usually wanting, and the diagnosis is rarely made during life.

ANEURISM OF THE ABDOMINAL AORTA.

Symptoms. The chief and most constant symptom is *pain* at a circumscribed spot in the abdomen, or diffused. Other symptoms depend upon the location of the aneurism, as they are the result of pressure. There is a gradual loss of health.

Inspection. Usually negative unless the aneurism reach an enormous size.

Palpation. A pulsating tumor in the abdomen to the left of median line. The pulsation is synchronous with the first sound of the heart, and is *expansile* (Corrigan's sign) in character.

Percussion. Dulness may be elicited if the tumor is large and the abdomen emaciated.

Auscultation. Rarely a murmur or bruit is heard, systolic in time. Diagnosis. Abdominal aneurism and pulsating abdominal aorta may be mistaken for each other. The point of difference is in the aneurism the presence of the tumor with an expansile pulsation, while in pulsating abdominal aorta the beating is like a pulsating cord, an up-and-down movement, not expansile. The condition of the patient is also important; aneurism in males, at middle life, with changes in the vessels; abdominal pulsation occurring in nervous women or effeminate men.

Tumors located over the abdominal aorta may give rise to an apparent pulsation, causing them to be mistaken for an aneurism. The rule is in all cases of abdominal pulsation to place the patient in the knee-chest position; if the tumor is aneurismal, the *expansile* pulsation continues; if not an aneurism but a cancer, impacted faces, or other tumor, the pulsation at once ceases.

Prognosis of Aortic Aneurisms. Unfavorable. The duration of life after the development of the aneurism is from one to four years.

Treatment. A persistent effort should always be made to promote clotting in the sac and the contraction of the tumor.

The so-called Tufnell's method is the most successful for this purpose, its aim being to diminish the force and rapidity of the circulation, and, if possible, to increase the fibrinous deposit. Its essential element is absolute rest of mind and body and a restricted diet; the patient is kept absolutely in bed day and night, for at least three months, and placed on the following diet: Breakfast—two ounces of bread with butter and two ounces of milk; dinner—two or three ounces of bread, same amount of meat, and two to four ounces of milk or claret wine: supper—two ounces of bread with butter and two ounces of milk. At the same time potassii iodidum is administered in increasing doses to the physiological limit.

Galvano-puncture is said to do good in some cases; two needles inserted into the aneurism are connected with the poles of a galvanic battery, and a weak current is passed through the tumor.

The various symptoms are to be met with their appropriate remedies, always having in mind the condition of the arterial wall allowing the rupture and dilatation.

DISEASES OF THE NERVOUS SYSTEM.

The diseases of the nervous system will be described under the following named headings:—

I. Diseases of the cerebral membranes. II. Diseases of the cerebrum. III. Diseases of the spinal cord. IV. Diseases of the nerves. V. General or nutritional diseases. VI. Mental diseases.

DISEASES OF THE CEREBRAL MEM-BRANES.

PACHYMENINGITIS.

Synonyms. Meningitis; hæmatoma of the dura mater.

Definition. Inflammation of the dura mater; when the external layer is primarily involved it is termed pachymeningitis externa; when the internal layer is primarily involved it is termed pachymeningitis interna.

Causes. Pachymeningitis externa is a surgical malady, excited by fractures, penetrating wounds, and other injuries of the skull.

Pachymeningitis interna is due to blows upon the head without injury to the skull. A predisposition may be created by chronic alcoholism, scurvy, Bright's disease, and syphilis. Chronic internal otitis and suppurative inflammation of the orbit may cause it, also inflammation in the venous sinuses the result of a thrombus undergoing suppurative changes.

Pathological Anatomy. Pachymeningitis interna. Hyperæmia of the membrane, followed by an exudation which develops into a membranous new formation, containing a great number of vessels of considerable size but having very thin walls. Hemorrages from these new vessels are of frequent occurrence, which increase the size and thickness of the neo-membrane.

The usual position of the neo-membrane or new formation is on the upper surface of the hemispheres, extending downward toward the occipital lobe. The changes in the adjacent portion of the brain are dependent on the size and thickness of the neo-membrane. Bartholow observed a case in which the "cyst" was half an inch in thickness at its thickest part, and it depressed the hemisphere correspondingly, the convolutions being flattened, the sulci almost obliterated, and the ventricle lessened one-half in size.

In Pachymeningitis syphilitica, the pathological lesion is in the form of gummatous tumors or masses which may degenerate and become either cheesy masses or be converted into a purulent-looking fluid.

In old age the dura mater becomes thick, cartilaginous, and of a dull white color. The sheaths of the arteries are also thickened.

Symptoms. Very obscure; principally those of cerebral pressure. Cases of persistent headache, vertigo, photophobia, anorexia, insomnia, gradual impairment of intellect and locomotion, followed by delirium, and convulsions and coma, or by apoplectic attacks and paralysis; in the aged, or those in whom some one of the causes of the affection are present, an inflammation of the dura mater may be suspected.

Circumscribed painful ædema behind the ear and less fulness of the jugular of the corresponding side, the *phlegmasia alba dolens en miniature* of Griesinger, are indicative of thrombosis in the transverse sinus, as was first shown by Virchow.

Diagnosis. Always problematical, as the symptoms are masked and so obscure that a positive diagnosis is impossible.

Prognosis. Most unfavorable for either forms, although the course of the malady is usually slow. Surgical treatment in traumatic cases offers some hope.

Treatment. Pachymeningitis externa is to be treated surgically. Trephining is indicated in some cases. It is claimed that benefit has followed a thorough course of *potassii iodidum*. In the great majority of cases, however, all that can be done is to treat symptoms.

ACUTE MENINGITIS.

Synonyms. Acute Leptomeningitis; cerebral fever; arachnitis. Definition. An acute exudative inflammation of the cerebral *pia mater and arachnoid membranes*, usually limited to the convexity of the cerebrum; characterized by fever, vomiting, headache, delirium, and followed by symptoms of general collapse.

Causes. During the course of the acute infectious diseases; erysipelas; associated with or a sequela of influenza. Cerebral overwork; prolonged wakefulness; acute alcoholism; exposure to the sun; disease of the internal ear; secondary to diseases of serous membranes. Most frequent in early adult life and in young children, and in males rather than females.

"The micro-organisms found in meningitis are the pneumococcus, streptococcus pyogenes, intracellular diplococcus, the pneumo-bacillus, and a bacillus resembling that of typhoid fever." (Dana.)

Pathological Anatomy. The inflammatory changes may be limited either to the *convexity* or to the *base* of the *brain*, but more frequently both portions are involved.

Intense hyperamia of both membranes, followed by a purulent and fibrinous exudation. The ventricles may be filled with fluid, compressing and flattening the convolutions.

In 25 post-mortem examinations at the Philadelphia Hospital a

meningo encephalitis was present in 14.

Symptoms. Vary according to the stages:-

Prodromes; headache, vertigo, cerebral vomiting, more or less feverishness, continuing from a few hours to one or two days, when occurs the

Stage of Invasion; onset sudden, with chill, high fever, 103°-104° pulse 100-120, face flushed, with congested eyes, headache, most intense and continuous, ringing in the ears, photophobia, vertigo, the nausea aggravated, projectile vomiting, with delirium.

Stage of Excitation; general sensibility of the body increased, sensitiveness to light, and acuteness of hearing, delirium furious, often resembling mania, continual jerking of the limbs, oscillations of the eyeballs—nystagmus—twitching of the muscles of the face, followed by powerful contractions of the flexor muscles, even to the extent of opisthotonos, and in children convulsions. Duration, from one day to a week or two.

The finger drawn across the surface leaves a red line, the tache cérébrale.

Stage of Depression or Collapse; the patient gradually becomes more quiet, the delirium subsiding, as well as the muscular agitation; somnolence develops, passing into coma, at times temporary consciousness, coma soon following again; pulse irregular and slow, fever less; various palsies, to wit: strabismus, ptosis, pupils uninfluenced by light, mouth drawn to one side, urine and fæces involuntarily discharged. Death following, either by convulsions or by deepening coma with cyanosis.

Diagnosis. The characteristic symptoms indicating the existence of acute meningitis are headache, vomiting, fever and delirium, all developing rather rapidly. The headache is most persistent, the vomiting not due to gastric trouble. The absence of any one of the four characteristic symptoms named above does not prove the absence of meningitis, nor does the combination of delirium and fever alone determine the presence of meningeal disease.

Cerebro-spinal fever closely resembles acute meningitis, the points of distinction between which are the first named occur-

ring epidemically, associated with marked spinal symptoms and an eruption.

Meningitis and abscess of the brain are apt to be mistaken for each other, the differential diagnosis being pointed out in that disease.

The cerebral symptoms of rheumatism are differentiated from idiopathic meningitis by the association of the joint trouble.

Cerebral symptoms of typhoid and typhus fever have a close resemblance to idiopathic meningitis, and are only determined by a study of the clinical history.

In acute uramia the face is turgid, cedematous, with puffiness of the eyelids; in meningitis the face is pale and no cedema; uramia has decided albuminuria; it is slight or absent in meningitis; meningitis has chills followed by fever; uramia has irregular temperature record rapidly rising to 104° F.–106° F., and dropping to 99° F., to as rapidly rise again, and usually associated with convulsions.

In *delirium tremens* the delirium is a busy one, the patient imagining persons and animals around him, and is wild in his gestures and utterances; the temperature is normal or subnormal, the skin wet and clammy. In meningitis the delirium is mild but incoherent, the surface is hot and dry, and there is severe vomiting and headache.

Prognosis. Not very favorable. If recognized early and treated, a fair number of recoveries occur, but it usually leaves the patient subject to attacks of epilepsy or with a persistent headache, and more or less mental impairment.

Treatment. Must be prompt and energetic from the onset.

At once, active purgation by oleum tiglii. gtt. ij, glycerinum, mv, dropped on the tongue; and if the urinary secretion be scanty, dry cups or digitalis poultices over the kidneys.

In vigorous subjects a copious venesection or leeches applied behind the ears, to the temples, or the nuchal region, followed by the application of cold to the head; that it may be thoroughly applied, the head should be shaven.

Control the active circulation by aconitum in full doses, frequently repeated, combined with potassii bromidum, gr. xx-xl, or use extractum ergotæ fluidum, f3ss-j every few hours. The cerebral circulation may be markedly influenced by compression of the carotids.

The apartment should be cool, the air pure, the patient's head elevated. The diet should be nutritious but easy of assimilation.

The secretions must be carefully watched, the catheter being frequently used during the stage of collapse.

For the vomiting use *chloral*, gr. iij-v, per mouth, diluted with aque menthæ f\(\frac{3}{2}\)ss, repeated in half hour and p. r. n., or by enema in doses of gr. x-xv. The most refractory vomiting, of whatever cause, will yield to a few doses of this drug.

If the case show a disposition to linger, small doses of hydrargyri chloridum mite or potassii iodidum are of benefit.

Third stage: Free stimulation, nutritious food, ferri iodidum and flying blisters.

TUBERCULAR MENINGITIS.

Synonyms. Basilar meningitis; acute hydrocephalus.

Definition. An inflammation of the leptomeninges (soft membranes), more particularly the basal pia mater, attended with or due to the deposit of gray miliary tubercle; characterized by gradual decline of the bodily and mental powers.

Causes. Usually a secondary affection, a sequel to tubercular disease of some other organ. Most frequently occurs in children between two and six years of age, although numerous cases are reported occurring between twenty and thirty years; scrofulous diathesis; inherited diathesis. The "gelatinous children of albuminous parents," as the phrase goes, possess a special susceptibility to tubercular meningitis.

Pathological Anatomy. The deposition of tubercle usually occurs at the base of the brain.

Depositions of grayish-white granules, of a translucent, somewhat gelatinous appearance—miliary tubercle, are distributed along the vessels of the pia mater, resulting in inflammation and the exudation of lymph, with the consequent thickening and opacity of the membranes.

The cerebral tissue is not usually involved, although on section the lines indicative of blood vessels are very much increased in number. The ventricles are distended by a clear, or milky, or even bloody serum.

Tubercular deposits occur in the lungs, intestines, and, at times, in other organs.

The presence of the tubercles alone may give rise to no symptoms until the exudative products of the resultant inflammation develop.

Symptoms. The advent is either gradual and insidious, or with convulsions, in which cases the after progress is rapid.

Prodromes: the child grows irritable, with loss of appetite, loss of flesh, swollen abdomen, constipation alternating with diarrhœa, irregular attacks of feverishness, with attacks of grinding its teeth during sleep, or sleeplessness. Headache occurs, as shown by the child, even when at play, suddenly stopping and resting its head on its hand or on the floor. Duration of this stage is from one week to a month or two.

Stage of excitation: the onset is rather sudden, with obstinate vomiting, severe headache, convulsions, fever, 102°-103° in the evening, falling to 99° in the morning, pulse soft and compressible, with irregular rhythm. On drawing the finger nail lightly over the surface a red line results, "the cerebral stain" of Trousseau. The symptoms grow progressively worse with exaltation of the special and general senses; the least pinch or even touch causing exquisite pain; spasmodic movements of the muscles, with contraction and rigidity, at times opisthotonos. Duration of this stage is about two weeks.

Stage of depression; the result of the pressure of the exudation; the pulse slow and compressible, with irregular rhythm; temperature depressed; tendency to somnolence alternating with quiet delirium, mental stupor, continual movement of the fingers, as in picking up objects; convulsions from time to time, strabismus, oscillation of the eyeballs, followed by intervals of wakefulness, when the headache is excruciating, causing the peculiar, unearthly shrill cry or shriek, "the hydrocephalic cry," associated with contraction of the muscles of the face, as if suffering were experienced; finally collapse, occurring with the "Cheyne-Stokes" respiration, the coma deepening, followed by death, convulsions often ending the scene. Duration, from a day or two to two weeks.

Diagnosis. Acute meningitis and tubercular meningitis have closely analogous symptoms during the stage of excitation, but the history and clinical course of the two maladies determine the diagnosis.

Prognosis. Unfavorable. Usual duration, three or four weeks after fully developed prodromes. If ushered in by convulsions the duration is shorter.

Treatment. Most unsatisfactory. No means of retarding the

disease. Treat symptoms as they develop. Blisters, leeches, active purgation, pustulating ointments, *potassii iodidum* and *hydrargyrum*, are all useless.

If the hereditary tendency be marked, nutritious food, oleum morrhuæ, ferri iodidum and quinina may somewhat delay the development of the affection.

DISEASES OF THE CEREBRUM.

CONGESTION OF THE BRAIN.

Synonyms. Cerebral hyperæmia; cerebral congestion.

Definition. An abnormal fulness of the vessels (capillaries) of the brain; active, when arterial fulness; passive, when venous fulness; characterized by headache, vertigo, disorders of the special senses, and if the hyperæmia be decided, convulsions.

Causes. Active. Increased cardiac action, the result of hypertrophy of the left ventricle; general plethora; excesses in eating and drinking; acute alcoholism; sunstroke; prolonged mental labor; diminished amount of arterial blood in other parts, the result of the compression of the abdominal aorta; ligation of a large artery, and the suppression of an habitual bleeding hemorrhoid are examples.

Passive. Dilatation of the right heart; pressure upon the veins returning the cerebral blood.

While congestion of the brain is not so common as was once supposed, the view that it cannot occur is disproven by the results following the inhalation of a full dose of amyl nitris. The relief of head symptoms after a free epistaxis and the distress resulting if it does not occur is another instance.

Pathological Anatomy. The post-mortem appearances are, overloading of the venous sinuses and of the meningeal vessels, including the finer branches; the pia mater appears vascular and opaque; the gray matter of the convolutions unduly red; the convolutions may be compressed and the ventricles contracted, with the displacement of a corresponding amount of cerebro-spinal fluid.

Long continued or repeated congestions lead to enlargement and

tortuosity of all the vessels, a moist and slimy condition (ædema) of the cerebral substance, and an increase in the sub-arachnoid fluid.

Symptoms. "Rush of blood to the head" may be gradual or sudden in its onset, the symptoms aggravated by the recumbent position. Headache, with paroxysmal neuralgic darts, disorders of vision and hearing, buzzing in the ears and sparks before the eyes, contracted pupils, vertigo, blunted intellect, inability to concentrate the mind, irritable temper and curious hallucinations. The face is red, the eyes congested, and the carotids pulsating. The sleep is disturbed by dreams and jerkings of the limbs. If the attack be sudden (apoplectiform), sudden unconsciousness with muscular relaxation occur.

Cerebral hyperæmia in children often presents alarming symptoms, such as great restlessness, insomnia, night terrors, gnashing of the teeth during sleep, vomiting, contraction of pupils followed by general convulsions. Any or all of these symptoms may continue more or less marked from an hour or two to a day, the child enjoying its usual health, after a sound sleep, save some fatigue.

Prognosis. *Mild cases* terminate favorably in a few hours to a day or two, but show a strong tendency to recur. *Severe cases* (apoplectiform) may terminate in health, but usually foretell cerebral hemorrhage.

The passive form is controlled by the lesions giving rise to it.

Treatment. Active form. Remove the cause if possible. Elevate the head and apply cold, either cold cloths or the ice cap, at the same time warmth to the feet. Leeches to the mastoid, or cups to the neck, or in the apoplectiform variety venesection, to diminish the intercranial blood pressure; compression of the carotids, or ligatures about the thighs, have been recommended.

An active purgation is indicated, either by oleum tiglii, or magnesii sulphas, by the mouth. The following enema is often valuable: (R. Magnesii sulphatis, $\overline{3}ij$; glycerini, $f\overline{3}j$; aquæ bul., $f\overline{3}iv$. M., and administer per rectum with little force)

In mild cases the application of an *ice cap* to the head, *sinapis* to the nucha, and *potassii bromidum*, gr. xxx-xl, repeated, and the enema mentioned, control the symptoms. *Extractum ergotæ fluidum* is strongly recommended, but its value seems to be overestimated.

In severe cases, with forcible overacting heart, to the above means must be added *tinctura veratri viridis* or *tinctura aconiti*.

Passive form. Becomes a part of the treatment producing the stasis.

CEREBRAL ANÆMIA.

Definition. An abnormal decrease in the quantity of blood in the cerebral vessels; *general*, when the diminished supply includes all the vessels; *partial*, when the diminished supply is limited in area; characterized by pallor, headache, vertigo, some loss of power, and, rarely, convulsions.

Causes. Partial cerebral anæmia results from obstruction of a vessel, from embolism or thrombosis. General cerebral anæmia results from hemorrhages, wasting diseases, during convalescence from severe attacks of fevers, sudden shock, feeble cardiac action and general anæmia.

Pathological Anatomy. The blood in the brain is contained in arteries, capillaries, and veins. The functional condition of the brain depends on the quantity and quality of the blood circulating in the cerebral capillaries. Any decrease in the normal quantity or impairment in the quality produces the symptoms of cerebral anæmia. The brain is pale and milky in color, and on transverse section there are no bloody points; the ventricles and perivascular lymph spaces are well filled with fluid.

In partial anæmia the local conditions differ somewhat from the above.

Symptoms. *General: headache*, relieved by the recumbent position; *vertigo*, aggravated by exertion; general *pallor* and anæmia, with attacks of *fainting*; when the general cerebral anæmia is sudden and decided, convulsions occur.

Partial anamia; sudden loss of power, of limited muscular area, gradually returning to the normal condition.

Prognosis. Favorable in all cases save those the result of severe and repeated hemorrhages.

Treatment. Regulated *nourishment*, with *stimulants*. A certain number of hours daily in the recumbent position is of advantage. When a tendency to attacks of *swooning* exists, stimulants or even the cautious inhalation of *amyl nitris* are indicated. To improve the quantity or quality of the blood—

CEREBRAL HEMORRHAGE.

Synonym. Apoplexy; "a stroke."

Definition. The sudden rupture of a cerebral vessel and escape of blood into the cerebral tissue, causing pressure and more or less destruction of the brain substance; characterized by sudden unconsciousness, irregular, noisy respiration and complete muscular relaxation.

Causes. Rare under forty years of age. The principal cause is disease of the vessels—the development of miliary aneurisms, or a chronic endarteritis with an associated cardiac hypertrophy; hereditary tendency; Bright's disease; syphilis; alcoholic and dietary excesses; gout. More frequent in the spring and autumn.

Pathological Anatomy. The most common locations of cerebral hemorrhage are the *internal capsule*, corpus striatum and thalamus opticus; less common the anterior and middle cerebral lobes and the cerebellum; next in frequency the pons and medulla oblongata; and rarely on the convexity of the brain, termed meningeal hemorrhage.

When the hemorrhage is large, the blood may break into the ventricles and pass by the *iter* from the third to the fourth ventricle.

A recent clot is dark in color, and in consistency a soft, grumous mass, composed of coagulated blood and brain substance in varying proportions, at whose centre is the opening into the ruptured vessel. The *clot* excites inflammation around it, resulting in its being encysted, by the development of new connective tissue from the neuroglia, and then gradually absorbed, leaving a cicatrix; or the brain tissue around the clot softens and degenerates—localized softening.

Symptoms. The attack may occur suddenly as an apoplectic shock or stroke or slowly with prodromes or "warnings."

Prodromes. Headache, vertigo, transient deafness or blindness, sensations of numbness of the extremities, with local palsies, together with the constant *dread of an attack*.

The attack begins with vomiting, followed by either partial or complete insensibility; respiration slow, irregular and noisy; during the inspiration the paralyzed cheek is drawn in, and puffed out in expiration; pulse slow and full; pupils uninfluenced by light, the face flushed, the eyes congested and the carotids throbbing; the temperature declines below the norm, a degree or two, but rises within twenty-four hours to 100° F.—101° F. In fatal cases the temperature may rapidly rise to 107° F.—108° F.

The muscular system is profoundly relaxed, and the reflex movements are abolished. The head and eyes deviate, in many cases, toward the affected side in the brain or from the paralyzed side. Rarely convulsions occur.

Ingravescent apoplexy begins as a mild stroke with a rapid return of consciousness and power, except, perhaps, of speech. Headache is present with some one or more local symptoms and in a few hours to a few days consciousness gradually becomes impaired, the loss of power again occurs, the coma deepens, the patient dying comatose.

If the unconsciousness continues longer than twenty-four hours, death is the usual termination, preceded by pale face, irregular and rapid pulse and respiration, and rise of temperature.

Reaction obtains in from a half to three hours, consciousness returning, reflex excitability reviving, associated with headache, confusion of mind, and more or less paralysis of motion and sensibility of one side of the body, termed—hemiplegia.

The electro-excitability of the paralyzed parts is preserved.

Recovery may be delayed by inflammatory symptoms, the temperature rising to 101°-104° F., with tonic contractions (early rigidity) of the paralyzed muscles and severe neuralgic pains.

Localization of the lesion of a cerebral hemorrhage is of great practical importance.

Capsular hemorrhage, the most frequent, causes loss of consciousness, of sudden or rapid onset, hemiplegia, involving face, arm, and leg, with motor aphasia if the hemiplegia be on the right side. There is also a unilateral loss of reflex action, conjugate deviation of the eyes from the paralyzed side and unilateral defective movement with flaccidity of the limbs.

Cortical hemorrhage, localized unilateral paralysis of the face, the arm, or the leg, with local convulsions or convulsions that have a local beginning, or profound unconsciousness.

Centrum ovale hemorrhages resemble the cortical with the local convulsions.

Crus-cerebri hemorrhage, loss of consciousness with hemiplegia involving the lower half of the face and the limbs, with paralysis of the third nerve on the opposite side, or the side of the lesion. The unilateral third nerve symptoms are ptosis, external strabismus, dilatation of the pupil, and loss of accommodation for near objects. The paralysis is termed "crossed" or "alternate" hemiplegia.

Pons hemorrhage causes either general convulsions or irregular convulsions in the legs, bilateral motor paralysis, bilateral anæsthesia, either contracted or dilated pupils, embarrassed respiration, repeated non-gastric vomiting and high temperature. If the hemorrhage is large, death is sudden or within a few hours, and even if small the prognosis is unfavorable.

Ventricular hemorrhages are generally of the ingravescent variety and are characterized by a second apoplectic seizure soon after the first, with extension of the hemiplegic symptoms or a relaxation of the muscles from one side to both sides of the body.

Cerebellar hemorrhage varies so greatly in the symptoms that a positive diagnosis can seldom be made.

Meningeal or dural hemorrhage, usually due to a trauma. Two varieties: I. Infantile meningeal hemorrhage, occurring during labor. II. Extra-dural hemorrhage the result of direct injury to the head.

The infantile variety presents symptoms of irritation and compression of the cortex such as convulsions, general or unilateral, rigidity, opisthotonos, and either hemiplegia or diplegia.

The extra-dural variety is almost always the result of fracture or trauma of the skull, resulting in an extravasation of blood between the dura and the skull from the middle meningeal artery; the hemorrhage may be on one or both sides. The symptoms may develop at once or after some days, and are those of pressure, hemiplegia, partial or complete, convulsions, impaired or absent reflexes, dilatation with loss of reaction of pupil of opposite side, stupor gradually deepening into coma and death.

Sequelæ. Paralysis of the muscles of the face, tongue, body and extremities of one side, opposite to the location of the hemorrhage, termed unilateral paralysis or right or left hemiplegia.

Paralysis of both sides of the body, due to simultaneous hemorrhage on both sides, termed bilateral hemiplegia, or diplegia.

Paralysis of one side of the face and the extremities of the opposite side, due to hemorrhage into the pons Varolii, termed alternating or crossed paralysis.

Occasionally tonic contractions occur in muscles long paralyzed, termed late rigidity, and is evidence of a secondary degeneration of

the nerve fibres.

Choreic movements in paralyzed muscles are termed post-hemiplegic chorea, due, according to Charcot, to changes in the motor centres.

The *mental powers* are always more or less permanently impaired, the patient irritable and emotional, and the same holds good concerning the *memory*.

Diagnosis. The diagnosis of the apoplectic seizure is often one of the most difficult questions in medicine, and yet of the greatest importance as the treatment hinges on it. The diagnosis of the sequelæ is comparatively easy.

Insensibility from drink differs from apoplexy in the following points, to wit: insensibility is not so complete, no drawing in and puffing out of one cheek with respiration, the pulse frequent instead of slow, the pupils influenced by light; upon raising both legs no difference is apparent on allowing them to drop; the eyes and head are not turned to one side, and lastly, the condition is ameliorated on the inhalation of ammonia. I have satisfactorily used Dr. von Wedekind's test for temulence, to wit: "By simply pressing on the supraorbital notches with a steadily increasing force you may, with certainty of success, bring an unconscious alcoholic to his senses, and thus differentiate between alcoholic and other comas."

Opium poisoning differs from apoplexy by the gradual approach of the coma, and that the patient can be momentarily aroused, and also by the absence of the heavy stertor of apoplexy.

Uramia causes a coma that closely resembles apoplexy. A history of Bright's disease at once clears up the case; again, uramic coma is generally preceded by convulsions, a rapid rise of temperature as shown by the thermometer, often 104° F. to 106° F., while to the hand the surface appears but little, if at all, above the normal; the pulse is usually weak with irregular force, the respirations averaging twenty-five to thirty per minute, the face having a glossy appearance.

Cerebral embolism cannot always be differentiated from apoplexy.

Cerebral embolism cannot always be differentiated from apoplexy. We may suspect cerebral plugging, if the patient be young; if he be

laboring under acute or chronic cardiac valvular trouble; if, within brief periods, several incomplete attacks have occurred before a complete comatose condition obtains; or, if hemiplegia results with passing or slight unconsciousness; or, if the phenomena are sooner or later followed by cerebral softening, as embolism and thrombosis are the most common causes of softening.

Syncope or a fainting-fit is of sudden onset, but being due to a failure of the circulation, the pulse is feeble, the face pale, the respiration quiet, and the duration of unconsciousness short, all the very opposite of an apoplectic attack.

Prognosis. If the patient survive the immediate effects of a cerebral hemorrhage, he is always in danger of a new attack, since the causes of the original attack still remain. Another attack or two is the usual course, a fatal termination ultimately occurring.

The *hemiplegia* is uncertain; a partial recovery may occur within a few months, or it may continue for years,

Treatment. If there are prodromal indications, the most prompt means of reducing the intra-cranial blood pressure is by venesection, followed by a brisk purgative; if the patient be weak, however, leeches to the mastoid, and potassii bromidum, gr. xl-lx, or extractum ergotæ fluidum, f3ss-j, may be substituted.

For the attack, loosen clothing, elevate the head, remove constrictions, place in a cool room, have perfect quiet, placing the patient sufficiently on his side, with the face somewhat downward, for the tongue and palate and secretions to fall forward instead of backward into the pharynx, and at once venesection, cold to head, a mustard foot bath, and oleum tiglii, gtt. j-iij, with glycerinum, gtt. xv, placed on back of tongue; if the pulse be full and strong, when consciousness is regained, either tinctura veratri viridis or tinctura aconiti is indicated.

If during the attack the face be pallid and the pulse irregular, and the patient is prostrated by the shock, stimulants and digitalis are indicated, with, perhaps, leeches to the mastoid and an enema of terebinthina.

For the secondary fever, either tinctura aconiti or tinctura veratri viridis; for the headache and delirium, camphora bromidum.

For promoting the absorption of the clot, keep the secretions active,

a good diet and a course of potassii iodidum or hydrargyri chloridum corrosivum, alternated with—

After two or three months a weak *galvanic current* applied directly to the brain, by placing an electrode on each mastoid process, promotes absorption.

For the paralyzed muscles, the faradic current applied by placing one electrode over or near the nerve innervating the muscle and the other over its belly, acts as a tonic, preventing wasting; it is assisted by hypodermic injections of strychninæ sulphas, gr. $\frac{1}{3}$ 6, three times a week.

CEREBRAL THROMBOSIS AND EMBOLISM.

Synonyms. Partial cerebral anæmia; occlusion of cerebral vessels; cerebral apoplexy (?).

Definition. The occlusion of a cerebral vessel, from the formation of a *thrombus*, or the presence of an *embolus*, thus causing *anæmia* of some portion of the brain; characterized by the gradual—when the result of thrombosis, and the sudden, when due to embolism—development of headache, vertigo, disorders of intelligence, with more or less complete insensibility and paralysis.

Causes. Thrombosis, or the formation of a clot in the vessel—an ante-mortem coagulation—is almost always the result of chronic endarteritis, as seen in the aged, together with a slowing and weakening of the blood current. Chronic alcoholism and syphilis are the usual causes when occurring in young adults.

Emboli, in the great majority of instances, result from an endocarditis—cardiac emboli; small particles of the exudation being carried into the circulation and deposited in the brain. Emboli may also be derived from aortic aneurism, or syphiloma of the great vessels.

Pathological Anatomy. The cerebral arteries may be obstructed by emboli or thrombi; the cerebral veins and sinuses by thrombi only. The changes in the cerebral tissue are those of anæmia of the part or parts supplied by the occluded vessels. The subsequent changes depend upon the anatomy of the vessels. If the obstructed

artery has anastomoses, the collateral circulation is soon established and the brain tissue assumes its normal condition. If, on the other hand, the occluded vessel be one of "Cohnheim's terminal arteries" -arteries without anastomoses-the blood in the whole extent of the occluded vessel coagulates, thus preventing the backward flow of blood from the surrounding capillaries and so obstructing collateral circulation, whence the anæmic tissue dies or undergoes necrobiosis, followed by yellowish-white softening; or, if the vessel beyond the seat of the occlusion remains pervious, blood flows back through the capillaries from the nearest artery or vein; the parts that a short time before were bloodless now become deeply engorged, the succeeding changes in the vessels permitting diapedesis of the red blood globules; the tissues which are undergoing disintegration are colored by the red globules, causing the appearances entitled "red softening." which after some weeks becomes "yellow softening," finally changing to "white softening," when there is a milky, or rather creamy, fluid mixed with masses or particles of broken-down nerve elements.

The vessel most commonly occluded is the *left middle cerebral artery*, which sends branches to the second and third frontal convolutions, the anterior and superior portions of the three temporal convolutions, the island of Reil, the parietal convolutions, part of the external and all of the internal capsule, the lenticular nucleus, and most of the corpus striatum,—the *motor centres*.

Symptoms. Two distinct modes of onset; gradual, when the result of thrombosis; sudden or apoplectic, when due to embolism.

Cerebral thrombosis. Most common in the aged. Persistent headache and vertigo, at one time severe and at another mild. Next, alterations in the patient's character; irritable, morose and despondent, with periods of absent-mindedness, disorders of vision, and impairment of memory, speech becoming hesitating and mumbling. Impaired locomotion, the result of the vertigo, and of muscular weakness and trembling, followed sooner or later by hemiplegia, which may be preceded by sudden insensibility or occur gradually, the symptoms slowly proceeding to senile dementia and death from exhaustion; or rarely, the symptoms are not so grave, and partial or complete recovery occurs after the hemiplegia, from establishment of the "collateral circulation."

Cerebral embolism. The symptoms are sudden, but either mild or grave in character.

Mild variety; sudden and severe vertigo, confusion of mind, muscular twitchings, usually one-sided, and vomiting, followed by hemiplegia, most frequently of the right side, the intellect clear but hesitating. After some weeks or months the paralysis usually disappears and recovery is complete.

Grave or apoplectic variety. Sudden headache, vertigo, flushing or pallor of the face, or the patient may utter a sharp cry, fall to the ground with sudden unconsciousness and complete muscular relaxation, followed by death, or a gradual return of consciousness with hemiplegia, which is generally right-sided, with aphasia, remaining for several weeks or months, or is persistent, the mind remaining normal or enfeebled and the emotional nature highly excitable and the reason and judgment clouded, continuing thus for years, or gradually developing into dementia, exhaustion and death.

The following are some of the symptoms of "localization" if particular vessels are blocked:

Vertebral artery, the left most frequently, results in acute bulbar paralysis from involvement of the nuclei in the medulla, associated or not with hemiplegia.

Basilar artery causes diplegia with bulbar symptoms. There is rapid rise of temperature. Death follows within a day or two, or suddenly, if respiratory centres involved.

Middle cerebral artery is the most frequent seat of embolic or thrombotic occlusions. The symptoms depend upon the exact branch involved: if plugged before the central arteries are given off, the internal capsule is deprived of its blood supply and permanent hemiplegia may follow: if the blocking is in the central branches the hemiplegia involves the arm and face, and if the left side aphasia occurs. The individual branches passing to the third frontal (aphasia), the ascending parietal (hemiplegia, particularly hand), supra-marginal and angular gyri (word blindness), and the temporal gyri (word deafness), may be plugged.

Duration. *Thrombosis*, essentially an affection of the elderly, has a chronic course. Months or years may be occupied with the various symptoms until the phenomena of senile dementia develop.

Embolism is of sudden onset, and may be followed by a rapid recovery.

Diagnosis. Thrombosis is associated with changes in the vessels, the arcus senilis and other evidences of senile degeneration.

Embolism may be mistaken for cerebral apoplexy, and while a positive differentiation cannot always be made, the chief point to be considered is the presence of cardiac murmurs.

Prognosis. Thrombosis is a permanent and progressive condition in the majority of instances. Recovery is a rare termination.

Embolism may be followed by a perfect recovery. Usually, however, some evidences of the plugging remain permanently. Death may be the result within a day or two, from the plugging of a large vessel, the patient never emerging from the coma. In other cases the patient arouses from the coma, the hemiplegia with aphasia persisting, and the case pursues the usual course of localized cerebral softening.

Treatment. The indication in the early stage of embolism and thrombosis is the reëstablishment of the circulation within the district deprived of blood-supply, in order to prevent the changes incident to defective nutrition; this is accomplished by means to strengthen the heart's action, tonics, perfect rest for some time after the attack, a plain but nutritious diet, and attention to the various excreta.

Prof. Bartholow "has had remarkable results from the following plan of treatment in thrombosis:" Ammonii carbonas, gr. x, with ammonii iodidum, gr. v, three times a day, continued for several months, "the object being dual—to increase the action of the heart and arteries and to effect a solution of thrombi forming by maintaining the alkalinity of the blood."

In the aged, presenting indications of degeneration, much benefit results from the use of—

It may be combined with oleum morrhuæ with decided advantage. For embolism, the immediate and persistent use of the following may dissolve the plug:—

R. Ammonii carbonat., gr. v Liquor. ammonii acetatis, f z j. M. Stg.—Three or four times daily.

"In a month or two a very light galvanic current (from two cups) may be passed through the brain in both directions" (Bartholow).

CEREBRAL ABSCESS.

Synonyms. Acute encephalitis; suppurative encephalitis.

Definition. An acute suppurative inflammation of the brain structure, either localized or diffused, primary or secondary; characterized by impairment of intellect, sensation and motion.

Causes. Primary cerebral abscess is exceedingly rare. Pyæmia; glanders: embolus from ulcerative endocarditis.

Secondary cerebral abscesses result from injuries to the cerebral tissues, to wit: apoplexy, embolism, thrombosis, and injuries to the cranial bones. Chronic ear disease; chronic suppuration in some other portion of the body.

Pathological Anatomy. Abscess of the brain affects the left side more frequently than the right. They are usually encysted or enclosed in a limiting membrane. Abscess of the brain may be single or multiple, varying in size from an almond to an egg.

It occupies a limited and well-defined region of the cerebral tissue, to wit: either corpora striata, optic thalami, gray matter of the cortex, the cerebellum, or the white matter of the hemispheres.

"The initial stage at the site of the abscess is hyperæmia. Minute extravasations take place (capillary hemorrhages), giving to the inflamed area a dark, reddish color, whence the term red softening. Migration of white corpuscles, diapedesis of some red corpuscles and exudation of serum holding albumin and fibre in solution, occur simultaneously. The brain tissue, being soft and easily broken up, is rapidly dissociated and its elements disintegrated, and in a short time a soft, pultaceous, red mass results, which more and more assumes a purulent character, becoming first reddish-yellow, then yellow or greenish-yellow, ultimately almost white. The injury caused by an abscess is not limited to the portion of the brain inflamed, but the neighboring territory is in the condition of collateral hyperæmia and cedema "(Bartholow).

Symptoms. A concise description of the symptoms of abscess of the brain is very difficult, on account of the wide variations dependent on its location, and also the difficulty of isolating it from the affections to which it is secondary.

The onset varies according to the cause, although all cases are associated with headache, irritative fever, vomiting, persistent and spread-

ing paralysis, convulsions, optic neuritis, mental apathy, delirium, and coma.

If following apoplexy, thrombosis, or emboli, there occurs fever and delirium, the paralysis remaining and spreading with spasmodic contractions of the affected muscles.

Occasionally cases run a chronic course, the onset rather insidious; dull, persistent headache, changed disposition, peevish, irritable, unreliable, with decline of moral sensibility; easily fatigued by mental work; inability to stand exertion; memory impaired; vertigo; dyspepsia, soon followed by slight palsies, which progressively increase, becoming general, with involuntary discharges, death following from exhaustion.

Of the focal symptoms, hemiplegia, of incomplete character, occurs in about one-half of all cases of abscess of the brain. A very constant symptom of diagnostic value, when hemiplegia is very marked, is exaggerated knee-jerk with pronounced ankle clonus.

Diagnosis. A positive diagnosis is only possible by a close study of the causes and the clinical history, as the symptoms at times indicate meningitis and again cerebral tumor.

Furulent meningitis may follow trauma to the brain or chronic ear disease, making the diagnosis impossible. The chief points of distinction are, the subacute or chronic course of abscess (rarely an acute course), slight involvement of cranial nerves, hemiplegia, and the presence of an active, persistent, unilateral ankle clonus and exaggerated knee jerk on paralyzed side.

Prognosis. The usual termination is in death. The course depends upon the character and extent of the injury, varying from a few days to several months.

Treatment. Surgical treatment has been attended with marked success in some cases of abscess of the brain, the withdrawal of the pus being followed by recovery. For traumatic abscess the operation of trephining is indicated. Symptomatic treatment for relief of the various symptoms as they arise.

INTRA-CRANIAL TUMORS.

Synonym. Cerebral tumors.

Definition. Tumor of the brain is either a growth in the cerebral tissue, on the meninges, or in the vessels; characterized by symptoms of pressure upon the brain structure.

Causes. Injuries to the head; syphilis; changes in the vessels; tubercle and cancer: heredity.

Pathological Anatomy. The size of tumors vary, and may become as large as an orange before they will give rise to symptoms.

Tumors of the brain are of various kinds, to wit: vascular tumors—aneurisms; parasitic tumors—cysticercus; diathetic tumors—tubercle or syphilis; accidental tumors—glioma.

Whatever the character of the growth, it produces irritation of the surrounding parts, and by pressure, destruction of the tissues, or it interferes with the arterial or venous flow.

Symptoms. Those common to tumors in general are, headache, persistent and increasing in intensity, defects of vision, even blindness, due to an optic neuritis, a very constant symptom; defects of hearing, taste and of speech, the result of paresis of the vocal cords; vertigo, associated with nausea and vomiting; convulsions, epileptiform in character, usually limited to one side of the body, occurring at regular intervals, or confined to the eyeballs (nystagmus), or one limb, with no loss of consciousness; palsies, beginning first as strabismus, ptosis and dilatation of the pupil, of the facial muscles, paraplegia and general hemiplegia; defects of sensibility, to wit: sensations of numbness, and coldness in the limbs and body. Occasionally disturbances of equilibrium manifested by a tendency to go backward or turn to the right or left; intellectual faculties well preserved until late in the affection, when the memory becomes impaired or lost for certain articles, and finally a gradually advancing imbecility.

Diagnosis. Rarely can a positive diagnosis be made. The following points will aid: long-continued, persistent headache, without appreciable cause, epileptiform convulsions, unilateral, without loss of consciousness, difficulty of vision, hearing and speech, associated with nausea and vomiting, and local and general palsies.

The location of the tumor may be determined by the more or less pronounced character of certain symptoms.

The diagnosis of the character of the growth can only be determined by a close study of the history.

According to Herter, "the indications that suggest that the tumor is a *syphilitic growth* are as follows:" Syphilitic history, symptoms of irritative disease of cortex rather than destructive evidences of rapid growth at the onset followed by a period of slow progress or stationary symptoms, gradual improvement under anti-syphilitic

treatment, development between twenty and forty-five years of age.

Indications suggesting tubercular growth are: family history of or tuberculosis in some other organ of the patient, rapid development of symptoms, indications of the growth in the cerebellum or in the pons, early appearance of the symptoms, especially before the tenth year, and history of injury to head.

Indications suggesting *sarcoma* or cancer are: the presence of a sarcoma elsewhere and rapidly failing health, with cerebral tumor symptoms in patient over fifty years.

Indications suggesting *glioma*: sudden loss of consciousness with exacerbation of all symptoms in the clinical history of cerebral tumor, cortex irritative symptoms as in syphiloma, developing under fifty years of age, and the absence of all evidences of tubercle, syphilis, sarcoma, and cancer.

The *focal* symptoms of intracranial tumors are so important in diagnosis that the following summary is given of symptoms caused by brain tumors:—

Prefrontal region. Mental impairment, pressure in central region, causing aphasia, Jacksonian epilepsy, and disturbances of smell.

Central region. Motor aphasia, monoplegia, partial anæsthesia, Jacksonian epilepsy.

Posterior parietal region. Word-blindness, homonymous hemianopsia, disturbed muscular sense.

Corpus callosum. Progressive hemiplegia.

Crus cerebri. Crossed paralyses of oculo-motor nerve and limbs. Corpora quadrigemina. Oculo-motor paralyses, reeling gait, possibly blindness and deafness.

Pons and medulla. Crossed paralyses of face and limbs, or tongue and limbs. Other lesions in cranial nerves.

Cerebellum. Marked cerebellar ataxia, vomiting, convulsions, coma.

Base, anterior fossa. Mental enfeeblement, and disturbances of smell and vision, exophthalmos.

Base, middle fossa. Impairment of vision; hemiplegia; oculo-motor disturbances.

Base, posterior fossa. Trigeminal neuralgia; neuro-paralytic ophthalmia; paralyses of the face and tongue; impaired hearing; crossed paralyses.

Diagnosis between cerebral Tumor and Abscess. Both may have any or all of the following symptoms: headache, vomiting, double optic neuritis, and mental failure. Tumor has in addition, marked focal symptoms, monoplegia, hemiplegia, paralysis of cranial nerves and marked optic neuritis; the absence of these favor abscess, or if hemiplegia the ankle clonus and knee-jerk is exaggerated. Fever and rigors point to abscess. The causes of abscess are very clear, those of tumor often uncertain.

Prognosis. Unless of syphilitic origin, unfavorable; but it is to be borne in mind that all syphilitic tumors of the brain do not have a favorable termination.

Treatment. Unsatisfactory. Mostly symptomatic. As benefit occasionally follows the use of *potassii iodidum*, gr. xx, three times a day, or *ext. ergotæ fld.*, f3ss-j, three times a day, continued until their physiological effects are produced, these remedies should be used in all cases, discontinuing them if no benefit follow.

The surgical treatment of tumors of the brain was given a great impetus from the report of the case operated upon in the practice of Hughes-Bennet. The surgical treatment is promising for the future.

APHASIA.

Definition. The inability to use spoken language or give vocal utterance to ideas.

Amnesic aphasia, or loss of the memory of words by which ideas

are expressed.

Ataxic aphasia, the inability to combine the different parts of the vocal apparatus for vocal expression, although the memory of words still remains, so that the afflicted person can write his ideas intelligently.

Agraphia, the inability to recognize and make the signs by which

ideas are communicated in written language.

Amnesic agraphia, the inability to combine the muscular apparatus—"writers' cramp."

Paraphasia, the mental state in which the wrong words are used to express the idea.

Paragraphia, the state in which wrong or meaningless written signs are used to express the idea.

Pathological Anatomy. The distinction between aphasia and aphonia must be clearly determined.

Aphasia is not the result of any one specific lesion, but occurs during the course of several, to wit: occlusion of certain cerebral vessels; cerebral hemorrhage; cerebral abscess or softening; meningitis; tumors; mental or moral causes; hysteria.

It is now almost definitely determined that lesions of the left middle cerebral artery, island of Reil, third frontal convolution, and parts of the corpus striatum, are associated in the production of aphasia. The lesions are usually upon the left side of the brain, the aphasia being associated with right hemiplegia.

Symptoms. The degree to which articulate language is impaired varies, from the loss of a few words to complete inability to communicate ideas. The intellect does not suffer in proportion to the loss of words; for, showing the individual an article, while he may miscall it, if you call it by name he will recognize it. This inability to convey thoughts is a source of great mental suffering, in some leading to a suicidal tendency.

A strange clinical fact is the strong tendency to profanity shown by aphasic patients.

Diagnosis. Aphonia, or loss of voice, should not be confounded with aphasia, or the inability to remember words.

Paralysis of the tongue, or inability to move this organ, thereby interfering with articulate language, should not be confounded with aphasia, which, as a rule, is not associated with paralysis of the tongue.

Prognosis. Controlled entirely by the cause. If the result of congestion of the brain or a syphilitic tumor, the prognosis is favorable. If associated with hemiplegia the clot may undergo absorption, and recovery follow. If associated with softening of the brain, however, the disease grows progressively worse.

Treatment. Depends upon the cause, which must be energetically treated, as the aphasia pursues a course parallel to the associated malady. Cases not associated with cerebral softening have regained the memory of words by a course of carefully conducted speech lessons.

Cases of aphasia of sudden occurrence are strongly diagnostic of injury due to a spicula of bone if a history of a head wound, or from the pressure of a clot, and the operation of trephining may be of benefit.

VERTIGO.

Synonym. Dizziness.

Definition. Vertigo or dizziness is a subjective state, in which the individual affected, or the objects about him, seem to be in rapid motion, either of a rotary, circular, or a to-and-fro character.

Causes. The etiology of an attack of vertigo depends upon the particular variety.

Ocular vertigo results from the paresis of one or more of the ocular muscles, eye-strain or astigmatism.

Aural or Auditory vertigo, or Ménière's disease, results from disease of the semicircular canals and cochlea. Ménière's disease properly so-called, is a sudden severe vertigo, the result of either a hemorrhage or a serous or purulent exudation into the semicircular canals.

Gastric vertigo is the most common variety, and results from either stomachic or intestinal dyspepsia, disordered hepatic function or constipation. "The mechanism of the vertigo is complex. There are two factors; one consists in the toxic effect of the imperfectly oxidized materials which accumulate in the blood; the other is reflex. An impression made on the end organs of the pneumogastric in the stomach is reflected over the sympathetic ganglia" (Bartholow).

Nervous vertigo is associated with migraine, sick or nervous headache, and is also caused by physical or nervous excesses, also by the immoderate use of tea, coffee, alcohol and tobacco. It is also a result of many of the organic diseases of the brain.

Senile vertigo is the result of the disordered cerebral circulation resulting from changes in the heart and vessels.

Symptoms. In all varieties of vertigo, the symptom of a sensation of objects moving around the patient, or the patient moving around objects which remain stationary, is present in some degree. The attack of giddiness comes on suddenly, with an indistinctness of vision and slight confusion of the thoughts. The patient may fall unless he grasps something to steady himself. Nausea and vomiting and cardiac palpitation with tinnitus aurium are often associated with the vertiginous sensations. There is no loss of consciousness.

In the ocular vertigo the attack is usually the result of reading, writing, sewing, or other close application of the eyes, the ordinary symptoms of vertigo being preceded by headache, nausea, specks before the eyes, and pain in the eyeballs.

In *Menière's disease* the vertigo is associated with serious *tinnitus aurium* and the vertiginous sensations are of various forms, such as a see-saw movement, a gyratory motion, right or left; a vertical whirl, or a sensation of rising and falling like unto the swell of the ocean. The symptoms are of long duration, becoming marked in paroxysms. The attack of aggravated vertigo is so sudden and overwhelming at times that the person is suddenly thrown to the ground as if struck with a blow, associated with nausea and vomiting. As the condition continues the character of the individual changes, becoming morose, irritable and suspicious.

Not all cases of Ménière's disease become permanent, but it may occur in isolated attacks, the interval being free from all sensations.

Gastric vertigo is by far the most frequent variety. Persons subject to vertigo of this kind live in constant dread of cerebral disease, which frequently results in true melancholia.

The vertiginous sensations usually occur during the course of well-marked and long-standing stomach and intestinal disorders, such as pain or oppression after meals, nausea, pyrosis, heartburn, frequent eructations and constipation or rarely diarrhæa. The abdomen is often distended with flatus. Great pain in the nucha is a very frequent occurrence. The attack may be associated with either hyperæmia or anæmia of the brain. The symptoms are not constant, but recur at intervals, sometimes remote, at others very close on each other.

In nervous vertigo the vertiginous symptoms are usually associated with more or less irritability of temper, restlessness and insomnia. The onset is sudden, after some one of the etiological factors. In megrim there is headache, nausea and vomiting. This form of vertigo often precedes or replaces the epileptic convulsion, it also often precedes softening of the brain.

In senile vertigo the vertiginous symptoms are the result of anæmia of the brain. The attacks are developed by any exertion, often by merely assuming the erect posture. There is a swimming sensation in the head, darkness falls on the eyes with a sensation of chilliness and prostration.

Diagnosis. The diagnosis of the various forms of vertigo can only be determined after a close study of the history and course of the attack. The existence of organic cerebral disease must always be kept in mind in solving any case.

Prognosis. This will be influenced by the variety of the vertigo.

The prognosis is favorable in ocular and gastric vertigo. Unless the result of organic disease the prognosis is good in nervous vertigo. In auricular vertigo the prognosis is fair, but in genuine Ménière's disease the prognosis is unfavorable, as it also is in senile vertigo.

Treatment. For ocular vertigo, rest for the eyes and properly adjusted glasses.

For cases of Ménière's disease rest in the recumbent position and the use of full doses of *quinina*, grs. x to xv, daily for a long period, as suggested by Charcot.

For gastric vertigo a careful regulation of the diet. At the beginning of the treatment it is often of great advantage to place the patient on an exclusively milk diet, gradually widening the variety as improvement occurs. In these cases a course of arsenicum is often serviceable. If the digestion be torpid, the use of tinctura nucis vomicæ is indicated. If the bowels are constipated, benefit is obtained from extractum cascaræ sagradæ fluidum. (R. Ext. cascaræ sagr. fld., f3j; glycerini, f3j; tinct. card. comp., f3ss; aquæ menthæ, f3ss. M. et Sig. One teaspoonful three times daily.)

For nervous vertigo the removal of the exciting cause and the use of such remedies as *ferrum*, *quinina* and *strychnina*, either alone or variously combined.

For senile vertigo, a highly nutritious but easily digested diet, the use of a good *spiritus frumenti* and a course of *hydrargyri chloridum* corrosivum or arsenicum with tinctura nucis vomicæ.

In all varieties of vertigo the habits of the patient must be most abstemious, excluding tobacco, tea, coffee, highly seasoned foods, malt liquors, and alcohol unless particularly indicated.

MIGRAINE.

Synonyms. Megrim; hemicrania; sick headache; bilious headache; blind headache.

Definition. A unilateral paroxysmal pain in the head, periodical, accompanied with nausea, often vomiting, intolerance of light and sound and incapability of mental exertion, the brain for the time being temporarily prostrated and disturbed.

Causes. In the majority of patients the nervous predisposition to migraine is inherited, but whether inherited or acquired, it commonly develops before the age of thirty.

Among the many exciting causes are disturbances of digestion, irritation of the ovaries or womb, worry, exacting mental labor, sexual excesses and insufficient sleep, and eye strain. The causes of many attacks, however, are wrapped in mystery.

Symptoms. Attacks of migraine occur in irregular paroxysms, the intervals between being free from pain or nervous disturbance.

For a day or two preceding the paroxysm, it will be ascertained, on close questioning, that there was a feeling of fatigue without apparent cause, heaviness over the eyes, with some flatulency and indigestion.

The attack proper is ushered in by chilliness, nausea, often vomiting, yawning and general muscular soreness, with intolerance of light, and noises in the ears and incapability for mental exertion and pain of a sharp, shooting character of great intensity and persistency localized most frequently in either the frontal, temporal or occipital regions of the left side; at the same time there is tenderness over the whole side of the head. Rarely the pain is felt on the right side and still more rarely on both sides at the same time. The nausea and other digestive symptoms may follow the onset of the pain instead of preceding it.

There is more or less disturbance of the circulation, temperature and secretions of the affected parts. At times there is marked contraction of the vessels, when the face is pale, the eyes shrunken and the pupils dilated; again, the vessels may be dilated, when the face is flushed, the conjunctivæ injected and the pupils contracted.

Motion, sound and light aggravate the acute suffering.

The attack may continue with more or less intensity for a few hours to two or three days, the average duration being twenty-four hours.

Diagnosis. The symptoms are so characteristic that an error seems impossible. It may, however, be confounded with anæmic headache, hyperæmic headache, dyspeptic or bilious headache and neuralgic or rheumatic headache. The pains of organic brain disease must be excluded.

Prognosis. While few cases of true migraine are permanently cured, the affection is free from danger to life. In a fair number of cases the susceptibility to attacks declines as the person advances in years, it being rarely seen after fifty years.

"Cases of migraine of the ophthalmic variety appear to be not rarely followed by general paralysis of the insane" (Herter).

Treatment. To abort an attack of migraine or dispel a paroxysm after its onset, any one or two of four remedies are almost infallible—one is a hypodermic injection of *morphinæ sulphas*, gr. $\frac{1}{4}$, with atropinæ sulphas, gr. $\frac{1}{120}$, or antipyrine, gr. xx, repeated in an hour or two; or phenacelin gr. x, repeated in an hour or two. In many attacks extractum cannabis indicæ fluidum, gtt. ij-iij, every half hour or hour for a number of doses, is curative.

A combination for attacks associated with contraction of the vesseis

₿.	Potassii bromid., . Morphinæ sulph.,													
	Codeinæ sulph., .	٠		٠	٠	٠	٠		٠		٠	٠	gr. j

	Aquæ menth. p.,	٠	0	٠				b		٠,		ad	f 3 ss. N	Æ.
SIG.	-Repeated p. r. n.													

The local use of menthol pencils eases the pain.

In the intervals between the paroxysms, measures to improve the general system should be used, and to overcome as far as possible any of the etiological factors in its production. For this purpose extractum cannabis indica, gr. 1/4, three times daily for several months, is highly recommended.

"If the disposition to the malady is inherited, the prophylaxis is very important, and should include diet, exercise, clothing, and the avoidance of all those conditions which tend to develop an abnormal excitability of the nervous system. The best results have been obtained from galvanization of the superior ganglia of the sympathetic; the positive pole over the ganglion and the negative on the epigastrium in the tetanic (contraction of vessels) form; and the poles reversed in the paralytic (dilatation of vessels) form." Bartholow.

ALCOHOLISM.

Varieties. Acute alcoholism; chronic alcoholism.

Synonyms. Acute variety, temulentia; mania-a-potu.

Chronic variety, delirium tremens; dipsomania or oinomania.

It would hardly be correct to consider these terms interchangeable; they are rather names applied to various conditions due to acute or chronic alcoholic poisoning. **Definition.** Alcoholism is the term used to designate the physical and mental phenomena induced by the abuse of alcohol.

Temulentia, meaning drunkenness; mania-a-potu is an acute mental derangement, occurring in those of strong neurotic tendencies; delirium tremens is an attack of delirium associated with tremors in persons with the numerous changes resulting from chronic alcoholism. Delirium tremens results in alcoholics suffering from some form of nephritis, preventing the elimination of some poison developed from the ingested alcohol. Dipsomania or oinomania, an alcoholic insanity in which an individual at longer or shorter intervals has paroxysms of alcoholic desires, between which he neither wishes nor craves alcohol

Causes. Predisposing causes are influences arising from unfavorable moral, social and personal conditions. Heredity.

Exciting causes are the immoderate use of alcoholic beverages, of which there are three groups: 1, spirits, or distilled liquors; 2, wines, or fermented liquors, and 3, malt liquors.

Pathological Anatomy. Acute alcoholism. The brain is the seat of an active hyperæmia; the mucous membrane of the stomach and duodenum is markedly injected and covered with a ropy mucus slightly tinged with blood, and the gastric juice is altered in quality and quantity. The kidneys are also the seat of an active hyperæmia.

Chronic alcoholism. In this condition of the economy there are no organs or tissues which do not present morbid changes. The gastro-intestinal mucous membrane presents the changes of chronic catarrhal inflammation; the liver, the first organ to receive the poison after the stomach, presents the changes of congestion, cirrhosis or fatty degeneration; the kidneys show chronic congestion and often the changes incident to chronic interstitial nephritis. The post-mortem results found in twenty-five cases of delirium tremens dving in the Philadelphia Hospital, were fourteen with the changes of interstitial nephritis, eight with chronic parenchymatous nephritis, and three with fatty kidney; all showed chronic gastric catarrh and changes in the myocardium and the arteries of the heart, brain and the aorta. The muscular structure of the heart may undergo fatty degeneration and the vessels the senile changes of the aged. The brain structure presents the changes of sclerosis in various stages, and there may be chronic meningitis and pachymeningitis with hæmatoma. The nerves are

altered, atrophied and hardened, and the neuroglia, vessels and ganglion cells of the spinal cord show similar changes.

Symptoms. Acute alcoholism, resulting from the use of a large quantity of alcoholic fluid, occurs with symptoms of mild intoxication, to drunkenness passing to acute delirium and acute coma. The condition begins with a period of exhilaration, passing to semidelirium and ending in an acute coma, when the breathing is stertorous, the face bloated and congested, the lips swollen and purplish, the pupils contracted, the pulse feeble and slow, the skin cold and clammy, the temperature depressed and frequently control of sphincters lost. An individual so affected is said to be "dead drunk."

The cases of ordinary drunkenness do not often pass beyond the stage of exhilaration ending in a mild coma or sleep.

Mania-a-potu, or acute alcoholic delirium, is the direct result of alcoholic excess in those engaged in a sudden debauch, or who have drunk alcoholic beverages very "hard" for a comparatively short period. The individuals grow more and more excitable, lose all desire for food, are unable to sleep, become the prey of horrible hallucinations—"the horrors"—finally terminating in mania which resembles delirium tremens in all save the tremor, which is absent.

Chronic Alcoholism. The condition to which this term has been given is truly a disease. It is the result of the continued use of alcoholic beverages until one or more of the morbid organic changes have occurred. These persons are markedly dyspeptic, with coated tongue, fetid breath and early morning vomiting, straining or retching, attended with much distress. There is a gradually developing muscular tremor, progressing to the ataxic gait, and insomnia. The face may either become pallid, flabby and bloated, with an imbecile expression, or swollen, rough and dusky, with great bladders under the eyes, with yellow injected conjunctivæ. There is headache, vertigo, and attacks of hallucinations; the memory grows weaker, the judgment less accurate, the moral sense blunted and the will power weak and erratic. These and many other symptoms add to the distress of the individual, which he attempts to overcome by the use of more and more of the poison.

Delirium Tremens. In the majority of instances delirium results from a prolonged debauch, in an old drinker. It begins by an increased tremor, insomnia, irritable, excitable manner, followed by the characteristic hallucinatious and illusions, during which snakes and

all forms of repulsive reptiles are seen, causing the most intense horror and abject fear. There also occur illusions of smell and hearing. This marked excitement is followed by great depression, the skin is cold and clammy, the pulse feeble, the muscular system weak, the mind in a condition of coma-vigil, and a febrile condition, typhoid in character, develops. *Uræmic* symptoms soon develop, the temperature suddenly bounding to 103° F. to 104° F., or 105° F. with albumin and casts.

The ordinary duration of an attack of delirium tremens is about two weeks in those recovering, although death may occur at any time from cardiac failure, uræmia, or alcoholic pneumonia. Convalescence dates from the beginning of refreshing sleep, the patient awakening with a clear mind and desire for food. Should the delirium subside, but the patient continue to mutter and pick at the bed-clothing, the tongue become dry and cracked and the regurgitation of dark brownish and bilious matter occur, the condition is critical and an early fatal termination may be expected.

Dipsomania or oinomania is the inherited or acquired mental condition which craves the drinking of intoxicating liquors. This is a true mental disease. It manifests itself in periodical attacks of excessive indulgence in alcoholic drinking, or this symptom of this sad disease may be replaced by other irresistible desires of an impulsive kind, such as lead to the commission and repetition of various crimes, the gratification of other depraved appetites, robbery, or even homicide. Imbecility and dementia frequently result.

The paroxysms at first occur at long intervals, but gradually the intervals become shorter and shorter until the individual entirely surrenders himself to alcoholic and other excesses.

Diagnosis. Profound drunkenness or alcoholic coma may and often is confounded with apoplectic and uræmic coma. Von Wedekind suggests the following method for diagnosing drunkenness; "By simply pressing on the supraorbital notches with a steadily increasing force you may, with certainty of success, bring an unconscious alcoholic to his senses, and thus differentiate between alcoholic and other comas."

The symptoms of chronic alcoholism often bear a close resemblance to the following maladies: general paralysis, disseminated sclerosis, paralysis agitans, locomotor ataxia, cerebral and spinal softening, epilepsy, dementia chronica, and nervous dyspepsia.

In individuals whose habits are secret the question of diagnosis is attended with considerable difficulty. Anstie lays much stress upon the importance of the following four points, diagnostic of chronic alcoholism; insomnia, morning vomiting, muscular tremor and causeless mental restlessness.

Prognosis. In acute alcoholism the prognosis is good if the patient is manageable.

In chronic alcoholism the organic changes, the direct result of the alcoholic habit tend to shorten life by the production of fatty heart, Bright's disease, insanity, impotence, epilepsy, melancholia and organic brain diseases. The danger in delirium tremens is heart failure or deepening coma. The association of chronic nephritis with delirium tremens, perhaps its cause, must always be taken into account in determining a prognosis. Acute lobar pneumonia is a very fatal complication of all forms of alcoholism.

Treatment. In deciding upon a plan of medication in any of the varieties of alcoholism the condition of the kidneys, heart and vessels must be considered. The treatment of a case of drunkenness requires no consideration, as the rapid elimination of the alcohol soon occurs if its ingestion be stopped. Liquor ammonii acetatis in large, frequently repeated doses, assists the elimination of the poison.

For mania-a-potu the immediate and complete withholding of alcoholic beverages is essential for its successful treatment. If the stomach will tolerate food, and usually it will, milk, diluted with liquor calcis, or Seltzer water, or hot beef tea strongly seasoned with capsicum, should be frequently administered, together with such cerebral sedatives as potassii bromidum, chloral, per mouth or rectum, or the hypodermic use of morphinæ sulphas., gr. 1/3, with either hyoscin hydrobromas, gr. $\frac{1}{100}$, or atropinæ sulphas., gr. $\frac{1}{100}$. If the attack be associated with symptoms of cardiac depression, brisk frictions, artificial warmth, stimulating enemata and hypodermic injections of strychninæ sulphas, gr. 1 repeated, or caffeinæ citras, gr. iii repeated. or digitalis, are indicated. "If chloral be inadmissible by reason of weakness of the circulation, paraldehyde may be substituted, in doses of from half a drachm to one drachm, repeated at intervals of from one to two hours until quietude is produced" (J. C. Wilson). Act on bowels and kidneys in all cases.

For the *collapse* following a lethal dose of alcohol, the stomach should be immediately emptied by emetics or the stomach tube or

pump and the organ washed out with warm water or coffee, the patient placed in the recumbent position and surrounded with artificial warmth, hot frictions to the lower extremities, the use of artificial respiration or the use of faradism to the thorax, inhalations of ammonia, hypodermic injections of digitalis, strophanthus or atropina. "The flagging heart may be stimulated by occasionally tapping the præcordia with a hot spoon—Corrigan's hammer" (J. C. Wilson).

An attack of acute alcoholism or mania-a-potu may often be aborted with *trional*, gr. xxx, repeated in two hours, or *chloralamid*, gr. xxx-xl. repeated.

Chronic Alcoholism.—The combine of symptoms termed chronic alcoholism, are the direct result of the continuous action of a single toxic principle, and no success of even a temporary kind can be expected unless the poison be withdrawn. The rapidity with which this can be accomplished is a question for the skill, judgment and experience of the physician to determine; the chief obstacle to its success will be found moral rather than physical. Next to the disuse of alcohol is the question of diet. Much progress will be made as the appetite and digestion improve, and so great attention should be given to it. The general health will also be benefited by fresh air, exercise, mental occupation and cold or tepid sponging and an occasional hot bath at bedtime. For the combination of symptoms of spirit craving, morning vomiting, muscular tremor, mental restlessness and insomnia, no drug is comparable with strychninæ nitras, either hypodermically twice daily or, what is preferable, per the stomach to secure its local action on the mucous membrane. If the insomnia be persistent, in spite of the foregoing treatment, the temporary use may be made of such remedies as chloral, morphina, paraldehyde, or extractum lupulin ethereal (gr. j-iij), or trional, gr. xxx, repeated. In many cases it is desirable, for its mental effect, if no other, to administer what the patient terms a substitute for his alcoholic beverages. The following is a good combination for that purpose :--

R .	Tincturæ nucis vom	icæ	2,								٠	o		f 3 ss	
	Tincturæ capsici, .														
	Ex. lupulini fld., .													fZ iij	
	Inf. gent. co.,					0								f 🖁 iss.	M.
SIG	—Dessertspoonful th	ree	or	fo	our	ti	me	es	da	ily	7 %	ve!	l	diluted.	

For the anæmia, loss of strength, and mental debility, benefit may follow the use of syrupus hypophosphitis cum strychninæ.

Delirium Tremens.—The patient should be isolated, have a skilful, sensible nurse, the quantity of alcohol entirely withdrawn or greatly reduced, supplied with easily digested nutritious diet, and remedies used to combat the excited nervous system. For this latter purpose no one combination is comparable with hypodermic injections of morphinæ sulphas, gr. $\frac{1}{120}$, or hyoscin hydrobromas, (gr. $\frac{1}{100}$), repeated p. r. n.; or trional, chloralamid or parallehyde; chloral in the following combination also acts well if the stomach be not too irritable:—

R.	Chloral,										3 ss	
	Tr. capsici,										f Z ss	
	Aquæ menth.	p.	,	٠						٠	f \mathfrak{Z} vss.	M.

SIG.—Tablespoonful every two hours until sleep, alternated with a cup of hot beef tea to which has been added a bolus of capsicum, gr. xx.

Care is necessary that a condition of *coma* be not produced by the remedies mentioned.

For depression and cardiac weakness the internal use of any one of the following drugs is serviceable: Strychninæ sulphas, caffeinæ citras, spiritus chloroformi, ammonii carbonas, tinctura strophanthus, or digitalis.

Dipsomania.—The management of these cases is much the same as has already been mentioned for chronic alcoholism, although the strychnina treatment should be given the preference.

Strict attention must be given to the skin, bowels and kidneys. If the heart be not depressed, the cautious use of *hot air bath* or hypodermic injections of *pilocarpinæ hydrochloras*, gr. ½, repeated at the onset of the mania.

HEAT STROKE.

Synonyms. Insolation; sun-stroke; thermic fever; coup-desoliel; heat exhaustion.

Definition. A depression of the vital powers, the result of exposure to excessive heat. The condition manifests itself as acute meningitis (rare), heat exhaustion (common), and as true sun-stroke.

Causes. Exposure to the influence of excessive heat, either to the direct rays of the sun or artificial heat in confined quarters, or diffused atmospheric heat without proper ventilation.

Among the predisposing causes, which act by lessening the power of the system to resist the heat, are great bodily fatigue, overcrowding and intemperance.

Pathological Anatomy. The action of the heat upon the system is so sudden, and the malady so rapid in its course, that structural changes have not developed. The left ventricle is firmly contracted (Wood). The right heart and vessels are gorged with dark fluid blood. All the tissues and organs of the body are in a state of great venous congestion. The blood is dark, thin, and either but feebly alkaline or decidedly acid, and its power of coagulability is destroyed. The post-mortem rigidity is early and marked.

Symptoms. Depending upon the variety.

Acute Meningitis, the result of exposure to heat is similar to that due to other causes.

Heat-exhaustion develops with a rapid feeling of weakness and prostration, the surface cool, the face pale, the voice weak, the pulse rapid and feeble, the respirations increased, the vision growing dim and indistinct, noises develop in the ears, the individual, overcome, becoming partially or completely unconscious. In some cases the attack of prostration is sudden, the person falling unconscious, with perhaps convulsions or tremors, and shrunken features.

Sun-stroke. The symptoms, developing suddenly, with or without prodromata, are, insensibility, with or without delirium, or convulsions, or paralysis, the surface flushed and hot, the conjunctivæ injected, the breathing either rapid and shallow or labored and stertorous, the pulse quick and either bounding or weak, and the temperature in the axilla ranging from 105°, to 108°, to 110°, with suppression of all glandular action. Death occurring, the result of asphyxia, or from a slow failure of respiration and cardiac action.

Diagnosis. It is of great importance, therapeutically, to distinguish at once between attacks of sunstroke and heat-exhaustion. Cases of sunstroke are to be differentiated from cerebral hemorrhage and alcoholic insensibility, for which purpose the clinical thermometer is indispensable.

Prognosis. Attacks of heat-exhaustion, if properly and promptly treated, favorable. The prognosis of sunstroke or heat-fever is unfavorable in the majority of cases, death resulting in from half an hour to several hours. Unfavorable indications are, increased temperature, cardiac failure, convulsions, absent reflexes, followed by complete muscular relaxation.

Favorable indications are, decline in surface heat and axillary or

rectal temperature, stronger pulse, increased depth of respirations, restored reflexes, and return of consciousness.

Treatment. Cases of heat-exhaustion are successfully treated by placing the patient in the recumbent position, with the head low, and the use of stimulants. If able to swallow, administer at once spiritus vini gallici, 3 ss-j, with tinctura opii deodorata, mxx-xxx, to be repeated p. r. n.; if he be unable to swallow, the remedies may be thrown into the rectum, or spiritus frumenti, strychninæ sulphas, and tinctura digitalis can be used hypodermically. As convalescence occurs tonic doses of quininæ sulphas and strychninæ sulphas should be prescribed.

For sunstroke, the indications for treatment are the very opposite. The patient is in imminent danger from the extraordinary temperature, and measures to reduce it must at once be instituted. Of these none give such excellent results as rubbing with ice, or the cold bath or cold pack, and cold effusions, cold enemata, and the hypodermic use of quininæ sulphas, or antipyrin. The tendency to subsequent rise of temperature is met by wrapping the patient in a wet sheet, or the repetition of the hypodermics mentioned if consciousness has not been regained, when they can be given by the mouth. If convulsions and restlessness occur, the hypodermic use of morphinæ sulphas, gr. ½-½, cautiously repeated, is successful. If symptoms of depression occur, the stomachic, rectal or hypodermic administration of stimulants is indicated, and strychninæ sulphas, gr. ½, repeated half hourly by the hypodermic method.

For convalescence, use quininæ sulphas, strychninæ sulphas or ferrum.

ACUTE HYDROCEPHALUS.

Synonyms. Acquired hydrocephalus; serous apoplexy.

Definition. Strictly speaking, hydrocephalus signifies water in the brain; but it is here restricted to the presence of a serous fluid in the arachnoid spaces, in the pia mater, in the ventricles, and in the brain substance (ædema); characterized by the more or less sudden development of cerebral excitation, followed by depression and usually death.

Causes. Most common between the ages of one and five, although it may occur at any age. "The predominance of the nervous system in the bodily conformation" is a strong predisposing cause. Among the exciting causes are unfavorable hygienic conditions, dentition, eruptive fevers, blows on the head, mechanical causes

preventing the return of the blood from the venæ Galeni and the right sinus, compression of the jugular vein, diseases of the right heart, and Bright's disease.

Pathological Anatomy. The effusion may be limited to the ventricles, although there is usually considerable distention of the subarachnoid spaces and ædema of the pia mater and neighboring portions of the brain, whence results more or less softening, especially around the ventricles. The choroid plexus is hyperæmic and may be the seat of minute extravasations.

Symptoms. There are three varieties of acute hydrocephalus with characteristic symptoms, to wit: *comalose*, *convulsive* and the *ordinary*.

Comatose variety, known also as "serous apoplexy," begins abruptly with the phenomena of apoplexy, the result of the sudden effusion. The pressure is usually so great on the medulla oblongata that it ceases to functionate, death resulting in a few hours, rarely lasting several days.

Convulsive variety, the result of Bright's disease or a general dropsy, is ushered in with headache, nausea and vomiting, followed in a day or two with convulsions, passing into coma, which usually terminates fatally, although rarely a remission may precede death for a day or two.

Ordinary variety, the most common in children, begins with feverishness, headache, vertigo, photophobia, restlessness, nocturnal delirium, insomnia, twitching and spasmodic contractions of the muscles and great hyperæsthesia of the skin. Such symptoms continue for several days, when convulsions occur, followed by death, or a continuance of the symptoms, followed by rigidity, stupor and death.

Prognosis. Unfavorable.

Treatment. An attempt may be made to remove the fluid by diuretics and full doses of potassii iodidum.

CONGENITAL HYDROCEPHALUS.

Synonym. Chronic hydrocephalus (?).

Definition. An excessive accumulation of the cerebro-spinal fluid—a cerebral dropsy—in the ventricles—internal hydrocephalus, or in the meshes of the pia mater—external hydrocephalus, or in both—mixed hydrocephalus; characterized by enlargement of the head and more or less pronounced nervous phenomena.

A disease of infants, or very young children.

Causes. Imperfect or arrested development of the brain or its membranes. Occurs in the offspring of tubercular, scrofulous or syphilitic parents. Inflammatory changes in the ventricles and ependyma.

Pathological Anatomy. Enlargement of the head is the chief external pathological condition, although there is no constant ratio between the size of the head and the amount of fluid, the quantity varying from an ounce to a pint or more. The liquid is transparent, of a straw color, containing a small amount of albumin and chloride of sodium.

If the quantity of fluid be small the ventricles are simply distended, if the amount be large the optic thalami and corpus striatum are depressed and flattened, the roof of the ventricles thinned and the foramen of Monro is greatly enlarged. The enlargement of the head may occur before birth and impede or prevent natural delivery, or the head may be normal at birth and increase afterward. As enlargement progresses the bones are so thinned as to be translucent, the fontanelles and sutures are widened, the lateral portions of the cranium project, the forehead bulges out over the eyes, and the orbital plates are depressed, forcing the eyes outward and downward, producing a variety of exophthalmos; the head has an irregular, triangular shape, the base of the triangle being the top of the head. The scalp being stretched by the pressure within, becomes tense and thin, and but scantily covered with hair, the veins which ramify in it are unusually prominent and large, and the entire head is elastic on pressure, from the amount of liquid beneath.

Hilton, in *Rest and Pain*, says, "In almost every case of internal hydrocephalus which I have examined after death I found that this cerebro-spinal opening (between the fourth ventricle and the spinal canal) was so completely closed that no cerebro-spinal fluid could escape from the interior of the brain; and, as the fluid was being constantly secreted, it necessarily accumulated there, and the occlusion formed, to my mind, the essential pathological element of internal hydrocephalus."

Symptoms. The increased size of the head, with the emaciated condition of the child, who seemingly eats well, is what first attracts the attention. The head appears too heavy, the eyes are prominent and have a downward direction, the face is devoid of expression, old

and wrinkled, the voice feeble; the mental development is not in keeping with the age. When the period for standing or walking arrives the power is found wanting. The further history is but a continuation and exaggeration of this, until *convulsions* occur, which sooner or later terminate fatally.

The course of congenital hydrocephalus is usually slow but progressively worse. The majority terminate within the first year; cases are recorded, however, of ten and fifteen years' duration.

Diagnosis. In rachitis the volume of the head is increased, due, in part, at least, to a deposit of calcareous matter on the exterior of the cranial bones. Rachitis may be mistaken for hydrocephalus in cases in which the amount of liquid is small. The differential diagnosis is based on the shape of the head, round in rachitis, square or triangular or with prominences in hydrocephalus; with the persistent downward direction of the eyes and the elasticity of the head on pressure.

Prognosis. Unfavorable. Arrest of progress and even cures have been reported. Spontaneous cures are reported following the accidental discharge of the fluid. But such reports are exceptional.

Treatment. The use of the finest aspirator needle to evacuate the fluid is fully justifiable. The proper situation for the puncture is the coronal suture, about an inch or an inch and a half from the anterior fontanelle. Firm but gentle compression of the cranium with adhesive strips should be made during the escape of the fluid and afterward. A few ounces of fluid only should be withdrawn at a time. The internal use of potassii iodidum is recommended.

All measures which tend to promote the constructive metamorphosis are to be used.

DISEASES OF THE SPINAL CORD.

SPINAL HYPERÆMIA.

Synonyms. Spinal congestion; plethora spinalis.

Definition. An abnormal fulness of the vessels of the meninges and cord; active when an arterial hyperæmia; passive when a venous

hyperæmia; characterized by pain in the back, with more or less pronounced disorders of sensation and locomotion.

Causes. Cold and exposure; arrested menses; arrest of habitual hemorrhoidal discharge; malaria; protracted erect posture; injuries to the back; certain spinal poisons, as strychnina, picrotoxinum, and alcoholic excesses.

Pathological Anatomy. Active. The post-mortem appearances are congestion of the meninges and cord, the same vessels supplying both, with numerous points of extravasation, due to the rupture of capillary vessels. The spinal fluid is increased in amount.

Passive. A general bluish discoloration, owing to the abnormal fulness of the large anastomosing vessels; the spinal fluid somewhat increased.

Symptoms. Active. Dull pain in the dorsal or lumbar region, shooting into the hips and thighs, persistent and increased by pressure; tenderness on motion; tingling sensations in the limbs and feet, and sometimes in the hands and arms; a feeling of constriction about the abdomen is often present, with rigidity of the abdominal muscles. Increased reflexes, with disorders of motility, and when the patient is in the recumbent position, jerking of the limbs. On attempting to walk it is accomplished with difficulty, from an incomplete loss of power.

If the upper part of the cord be affected, dyspnæa and palpitation occur.

There often occur painful priapism and frequent nocturnal emissions.

The above symptoms may be followed by a more or less pronounced temporary depression, the sensation diminished and the lower limbs benumbed and heavy, the movements weak.

The electro-contractility is preserved, and in many cases even increased or exaggerated.

Duration. From a few hours to several days; if longer, myelitis may result.

Diagnosis. Anamia causes more or less spinal irritability and tenderness; but the history, pallor and general weakness, unassociated with defects of motility or sensibility, will prevent error.

Spinal meningeal hemorrhage is more sudden in its onset, its violence and its range of symptoms.

Myelitis and spinal meningitis have symptoms in common with

spinal congestion, which will be pointed out when discussing those affections.

Prognosis. Favorable, recovery occurring in three or four days. If the symptoms show a tendency to linger, myelitis, more or less pronounced, will ensue.

Treatment. Rest, but avoid lying on the back; cups or leeches along the spine, followed either by the iced or the hot douche, or hot sponges, with active purgation, to diminish the blood pressure.

If the result of suddenly arrested perspiration, pilocarpus and a hot airbath. If following suddenly arrested menses, aconitum. If associated with an active circulation, potassii bromidum, or extractum gelsemii fluidum, mv, every four hours, or extractum ergotæ fluidum, f3ss-j, repeated p. r. n.; and in all cases active purgation.

For the passive form, treating the cause, ergota, digitalis, tonics and purgatives.

PACHYMENINGITIS SPINALIS.

Synonyms. Pachymeningitis spinalis interna; hypertrophic pachymeningitis; pseudo-membranous pachymeningitis.

Definition. An inflammation of the inner surface of the spinal dura mater; characterized by violent pains in the head, neck, shoulders and arms, followed by contractures and paralyses of the upper extremities.

Causes. Exposure to cold and damp; alcoholism; syphilis; gout; injuries.

Pathological Anatomy. Hypertrophic pachymeningitis is characterized by an exudation upon the inner surface of the dura mater, which gradually solidifies into a layer of compact connective tissue, which presses upon the spinal cord and nerves, producing a myelitis and an atrophic neuritis, resulting in muscular atrophy.

The most frequent seat of this form of the affection is the cervical region, as first demonstrated by Charcot, whence the term cervical hypertrophic pachymeningitis.

In the *pseudo-membranous* form a membranous exudation also occurs, in which large numbers of blood vessels develop and rupture, the hemorrhagic extravasation forming a cyst—hæmatoma—which causes pressure on the cord and nerves.

Symptoms. The onset is slow and gradual, with irregular chills

and feverishness, violent pains and stiffness in the head, neck, shoulders and arms, continuous but subject to exacerbations, and associated with a painful constriction of the upper thorax. Numbness and prickling occur in the arms, more marked in one than the other. Rarely nausea and vomiting occur. These symptoms may continue off and on for several months, the muscles of the painful parts atrophying, followed by spasmodic contraction, particularly of the hands and wrists, followed later by paralysis.

The paralytic stage develops gradually, with weakness in the arms, associated with contractures and rigidity. The pain continues with anæsthesia, hyperæthesia and trophic changes. Later paraplegia with rigidity, exaggerated reflexes and spinal epilepsy, develop.

The development of tuberculosis and nephritis during the progress of chronic cerebral and spinal diseases, which are the immediate cause of death, is a clinical observation.

The electro-contractility is lost,

Prognosis. If early recognized and promptly treated, the hypertrophic form may be improved. Generally, however, the prognosis is unfavorable.

Treatment. Rest; nutritious diet; oleum morrhuæ and the hypophosphites; large doses of potassii iodidum, and repeated but systematic counter-irritation.

Symptomatic remedies for the pain and spasms are indicated.

SPINAL MENINGITIS.

Synonym. Leptomeningitis spinalis.

Definition. Inflammation of the arachnoid and pia mater membranes of the spinal cord, either acute, subacute or chronic; characterized by pain in the back, rigidity of the muscles, disorders of motility and sensibility. It may be acute or chronic.

Causes. The disease is rare and is always due to an infection from tubercle, syphilis, typhoid fever or septicæmia, or the result of a traumatism.

Pathological Anatomy. Acute. Hyperæmia of the membranes, with swelling of the tissues, the result of serous infiltration, followed by purulent and fibrinous exudations. The roots of the spinal nerves are covered with exudation, and are swollen and soft. The cord proper is more or less congested and ædematous.

Chronic. Adhesion of the membranes, with more or less accu-

mulation of fluid, resulting in atrophic degeneration of the cord from pressure.

If the disease is secondary to tubercle, these granulations are seen distributed over the pia, arachnoid, and inner surface of the dura.

Symptoms. There are two stages, the first, the stage of *irritation*, the second, the stage of *paralysis* of motion and sensation, with atrophy. Although an inflammatory affection, yet its onset is usually subacute, the febrile reaction being moderate, with intense boring pain in the back, aggravated by motion, rigidity of the spine and a sense of constriction around the body,—"the girdle." Spasmodic contractions of the muscles enervated by the nerves originating at the seat of the lesion, with inability to straighten the limbs. If the lower part of the spinal membranes are the seat, there occur retention of urine and constipation; if upper part, dysphagia, dyspnaa and feeble heart. The muscular contractions are excited or increased by motion, but uninfluenced by pressure. Reflex movements are not abolished. The rigidity and spasmodic contraction of the muscles are followed by paralysis, more or less complete, death following from paralysis of the muscles of respiration.

If the inflammation extend to the medulla, the above symptoms are associated with disorders of speech, vomiting and delirium.

Electro-contractility lessened or absent, both as to motility and sensibility, in the affected parts.

Chronic form succeeds to the acute or originates spontaneously, and presents the same form and order of symptoms—excitation or irritation, and depression or paralysis.

Diagnosis. The points of importance are, deep, boring pain in the back, aggravated by motion but not by pressure, with spasmodic contraction of the muscles, followed by paralysis.

Myelitis slight or absence of pain with earlier and more complete paralysis.

Tetanus may be confounded with spinal meningitis. The points of distinction are: in the former occur early trismus with rhythmical spasms excited by irritation of the skin, whereas irritation of the skin does not in spinal meningitis produce muscular contractions, but movement of the limbs does do so; progressively increasing, and not associated with fever; usually a clear history of an injury.

Prognosis. Generally unfavorable. Death is either sudden, from

paralysis of respiration and of the heart, or gradually, the result of exhaustion.

Critical discharges, such as profuse perspiration, urinary flow or epistaxis occur, and are followed by rapid recovery. Cases recovering may have more or less pronounced partial or complete paralysis.

Treatment. Rest in bed, upon the side or face. Cups or leeches along the spine, followed by ice, the hot douche, hot sponges or mustard. Active purgation.

If the result of syphilis, full doses of *potassii iodidum*, (gr. x-xl), combined with *hydrargyri chloridum corrosivum*, (gr. $\frac{1}{24}$ - $\frac{1}{12}$).

For the paralytic stage, quininæ sulphas, gr. iij, with extractum belladonnæ alcoholic. gr. $\frac{1}{4}$, three times a day, is sometimes useful.

For paralysis, the *galvanic current* to the spine and nerve trunks, and the *faradic current* to the affected muscles, with the deep injection of *strychnina* and the use of *massage*.

ACUTE MYELITIS.

Synonyms. Acute or general diffuse myelitis; transverse myelitis; softening of the cord.

Definition. An inflammation affecting the substance of the spinal cord, which may be limited to the gray or white matter, and involve the whole or isolated portions of the cord. When the gray matter alone is inflamed, it is termed central myelitis; when the white matter and the meninges, it is termed cortical myelitis; it may be ascending, descending or transverse in its extension. The disease is characterized by more or less sudden and complete loss of motion and sensation.

Causes. Following spinal meningitis; exposure to cold and damp; *injuries* to the vertebræ; prolonged functional activity of the cord; typhus fever; rheumatism; *syphilis*; puerperal fever, or during the course of the exanthemata; arsenical or mercurial poisoning.

Pathological Anatomy. Intense hyperæmia of the substance of the cord, with extravasations, giving the tissues a reddish-brown or chocolate tint, and also serous transudations, resulting in softening of the structure of the cord, the color changing to yellow and white, the nerve elements undergoing fatty degeneration, presenting the appearance and consistency of cream. The membranes also undergo more or less change.

Symptoms. The severity of the symptoms depends upon the extent and location of the inflammation.

The onset is usually sudden, with a chill, fever, 103°, frequent pulse, with alterations in sensibility and motility, to wit: pain in the back, aggravated by touch and by heat and cold, with sensations of formication, ("pins and needles"), the limb feeling as if asleep, or else complete anæsthesia, associated with severe neuralgic pains.

The distinction between anæsthesia, insensibility to touch, and analgesia, insensibility to pain, must be clearly determined.

A sensation of constriction around the body and limbs, as if encircled by a tight cord, "the girdle pains;" rapidly developing paraplegia, complete in a few hours, with involuntary discharges. The reflex functions are usually abolished, as seen by attempting to cause movement of the limbs by tickling the feet or by striking the patella tendon; rarely are they diminished, very rarely exaggerated. The temperature of the affected limbs is lowered three or four degrees.

Sloughs and bedsores and muscular atrophy result if the anterior cornua—the trophic centres—are affected.

The above symptoms of loss of motion and sensibility with rectal and vesical paralysis, are associated with more or less pronounced vomiting, hepatic disorders, irregularity of the heart, dyspnœa, dysphagia, apnœa and painful priapisms. The urine is markedly alkaline in reaction, finally developing cystitis.

Among the late manifestations are *shooting pains* and *spasmodic twitchings* or *contractions* of one or all of the muscles of the paralyzed parts.

The electro-contractility is abolished in the paralyzed parts.

Diagnosis. Acute spinal meningitis is distinguished from acute myelitis by severe pains, increased by pressure, with muscular contractions increased by motion, followed by paralysis much less profound than the paraplegia of myelitis; in spinal meningitis there exists cutaneous and muscular hyperæthesia, which is absent in myelitis.

Congestion of the spinal cord is characterized by the mild character and short duration of all the symptoms.

Hemorrhage in the spinal canal is abrupt, with irritative symptoms, slight paralysis, preserved reflexes and electro-contractility.

The principal diagnostic points of acute myelitis are the "girdle" around the limbs or body, rapid and complete paraplegia, loss of sen-

sation, lowered temperature in the affected parts, early and persistent sloughing (bedsores) and alkaline urine or cystitis.

Hysterical paraplegia shows no trophic changes, no altered reflexes, slight atrophy, irregular anæsthesia and the presence of the stigmata of hysteria.

Lithæmic paræsthesia, tingling and numbness of fingers and toes, might lead to error if the cerebral symptoms of lithæmia are overlooked.

The diagnosis of the location of the lesion is made by a study of the height of the anæsthesia, the skin reflexes and the distribution and extent of the paralysis, which are shown in the following table from Dana, based on that originally devised by Starr and modified by Mills and Dana.

LOCALIZATION OF THE FUNCTIONS OF THE SEGMENTS OF THE SPINAL CORD.

SEGMENT.	Muscles.	REFLEX AND CENTRES.	Sensation.
First cervical.	Rectus laterales. Rectus capitis. Anticus and posticus. Sterno-hyoid.		
Second and third cervi- cal.	Sterno-thyroid. Sterno-mastoid. Trapezius. Scaleni and neck. Omo-hyoid. Diaphragm.	Hypochondrium (?). Sudden inspiration produced by sudden pressure beneath the lower border of ribs.	Back of head to vertex and neck. (Occipi- talis major, occipi- talis minor, auricu- laris magnus, super- ficialis colli, and su- praclavicular.)
Fourth cervical.	Diaphragm. Deltoid. Biceps. Coraco-brachialis. Supinator longus. Rhomboid. Supra- and infra-spinatus.	Pupillary (fourth cervical to second dorsal). Dilatation of the pupil produced by irritation of neck.	
Fifth cervical.	natus. Deltoid. Biceps. Coraco-brachialis. Brachialis anticus. Supinator longus. Supinator brevis, Deep muscles of shoul- der-blade, Rhomboid. Teres minor. Pectoralis (clavicular part). Serratus magnus,	Scapular (fifth cervical to first dorsal). Irritation of skin over the scapula produces contraction of scapular muscles. Supinator longus. Tapping the tendon of the supinator longus produces flexion of lorearm.	Back of shoulder and arm. Outer side of arm and forearm to the wrist. (Supraclavicular, circumflex, external cutaneous, internal cutaneous, posterior spinal branches.)

LOCALIZATION OF THE FUNCTIONS OF THE SEGMENTS OF THE SPINAL CORD.—Continued.

SEGMENT.	Muscles.	REFLEX AND CENTRES.	Sensation.
Sixth cervical.	Biceps. Brachialis anticus. Subscapular. Pectoralis (clavicular part). Serratus magnus. Triceps. Pronators. Rhomboid.	Triceps (fifth to sixth cervical). Tapping elbow tendon produces extension of forearm. Posterior wrist (sixth to eighth cervical). Tapping tendons causes extension of hand,	Outer side and front of forearm. Back of hand, radial distribution. (Chiefly external cutaneous, internal cutaneous, radial.)
Seventh cervical.	Latissimus dorsi. Triceps (long head). Extensors of wrist and fingers. Pronators of wrist, Flexors of wrist, Subscapular. Pectoralis (costal part). Serratus magnus, Latissimus dorsi. Teres major.	Anterior wrist (seventh to eighth cervical). Tapping anterior tendons causes flexion of wrist. Palmar (seventh cervical to first dorsal). Stroking palm causes closure of fingers.	Radial distribution in the hand. Median distribution in the palm, thumb, index, and one-half middle finger. (External cutaneous, internal cutaneous, radial, median, posterior spinal branches.)
Eighth cervical.	Triceps (long head). Flexors of wrist and fingers. Intrinsic hand muscles.		Ulnar area of hand, back and palm, inner border of forearm. (In- ternal cutaneous, ul-
First dorsal.	Extensors of thumb. Intrinsic hand muscles. Thenar and hypothenar muscles.		nar.) Chiefly inner side of forearm and arm to near the axilla. (Chiefly internal cutaneous and nerve of Wrisberg or lesser internal cutaneous cutaneous.
Second dor- sal.			Inner side of arm near and in axilla. (Inter-
Second to twelfth dor- sal.	Muscles of back and abdomen. Erectores spinæ.	Epigastric (fourth to seventh dorsal). Tick-ling mammary region causes retraction of the epigastrium. Abdominal (seventh to eleventh dorsal). Stroking side of abdomen causes retraction of belly. Vasomotor centres. Second dorsal to second lumbar.	costo-humeral.) Skin of chest and abdomen, in bands running around and downward, corresponding to spinal nerves. Upper gluteal region. (Intercostals and dorsal posterior nerves.)
First lumbar.	None.	Cremasteric (first to third lumbar). Strok- ing inner thigh causes retraction of scrotum.	Skin over groin and front of scrotum. (Ilio-hy- pogastric, ilio-ingui- nal.)
Second lu m - bar.	Vastus internus.	Patellar. Striking pa- tellar tendon causes extension of leg.	Outer side and upper front of thigh. Lum- bar region, (Genito- crural, external cuta- neous.)

I.OCALIZATION OF THE FUNCTIONS OF THE SEGMENTS OF THE SPINAL CORD.—Continued.

SEGMENT.	Muscles.	REFLEX AND CENTRES.	Sensation.
Third lumbar.	Sartorius; adductors of thigh.		Front and outer side of thigh. Inner side of
Fourthlum- bar.	Flexors of thigh. Extensors of knee. Abductors of thigh.	Gluteal (fourth to fifth lumbar) Stroking buttock causes dimpling in fold of buttock.	leg and foot. Inner side of thigh, leg, and foot. (Internal cutaneous, long saphe- nous, obturator.)
Fifth lumbar.	Outward rotators, Flexors of knee, Flexors of ankle, Peronei, Extensors of toes.	Achilles tendon. Over- extension causes rapid flexion of ankle, called ankle clonus.	Back of thigh and outer side of leg and ankle; sole; dorsum of foot (External popliteal, ex- ternal saphenous, mus- culo-cutaneous, plan- tar.)
First and second sacral.		Plantar (fifth lumbar to second sacral). Tickling sole of foot causes flexion of toes and retraction of leg.	Back of buttock and thigh, side of leg and ankle; sole; dorsum of foot.
Third, fourth, and fifth sa- cral.	Perineal. Muscles of bladder, rectum, and external genitals.	Genital centre. Vesical centre. Anal centre.	Circumanal region, anus, rectum, penis, urethra, vagina, perineum. (Small sciatic, pudic, inferior hemorrhoidal, inferior pudendal.)

Prognosis. Varies according to the location of the lesion and completeness of the symptoms.

If the paralysis is of the ascending variety, death occurs within a few days, from paralysis of the muscles of respiration.

If the *trophic centres* are affected, there occur bedsores, intense pyelo-nephritis and cystitis and changes in the joints; death from exhaustion, in several weeks.

Central myelitis, or inflammation of the gray matter, is rapid in its progress, death occurring in a week or two.

The morbid process may be arrested and the general health restored, but some spinal symptoms will persist.

Treatment. Absolute rest is essential to even secure a palliation of the symptoms.

Locally, considerable relief follows the use of hot-water bags or sponges dipped in hot water and applied along the spine every few hours.

The remedies most strongly recommended are: digitalis, strychnina

ergota, belladonna, bromides, cimicifuga and quinina, although I have never observed a cure with any plan of medication, after the disease was fairly established, save those due to syphilis, by large doses of potassii iodidum. Gray reports having administered 700 grains daily before improvement began.

INFANTILE SPINAL PARALYSIS.

Synonyms. Myelitis of the anterior horns; poliomyelitis anterior acuta; essential paralysis of children; atrophic paralysis of children.

Definition. A rapidly developed inflammation of the anterior horns of the gray matter of the cord, occurring suddenly in children, at times in adults—acute spinal paralysis of adults;—characterized by mild fever, muscular tremors and twitchings, and paralysis of groups of muscles.

Causes. Essentially a disease of early life—the second month to the third or fourth year. The fact of its having occurred in adults must be borne in mind. Cold and damp; dentition (?); injuries to the spine; developed during convalescence from the acute exanthemata.

Pathological Anatomy. The early changes are: medullary hyperæmia, vascular exudation and inflammatory softening, although the naked eye may not recognize any changes. Microscopical examination reveals inflammatory softening of the anterior horns of the gray matter. Among other constant lesions are atrophic degeneration of the multipolar ganglion cells and of the anterior nerve roots.

The changes noted as occurring in the cord are usually limited to the dorso-lumbar and cervical enlargements.

As a direct result of the changes in the *trophic centres* and the nerve degeneration of the muscular fibres supplied, there ensue changes in the bones and joints, leading to great deformities.

Symptoms. The onset of the affection varies; it may be acute, sub-acute or chronic; it is usually sudden, with an attack of mild fever of a remittent type, of a few days' duration, on recovery from which it is noticed that the child is paralyzed. Rarely the paralysis may be preceded by convulsions.

The paralysis may affect both arms and both legs, the legs alone, or only one of the four extremities; it may, but very rarely, be a

hemiplegia. As a rule, however, the leg suffers more frequently than the arm: in paralysis of the leg the muscles below the knee suffer more severely than those above. The bladder and rectum are not affected, or if so, only temporarily, nor can anæsthesia or numbness be detected. The temperature of the paralyzed limb is low and the appearance cyanosed. After a few days there is a slight improvement in the paralyzed parts, although the muscles show a rapid wasting, which is progressive until all muscular tissue is gone.

The reflex movements are impaired or abolished.

The *electro-contractility* by the faradic current is *abolished* in the paralyzed parts.

With the *galvanic* or constant current the "reactions of degeneration" are developed. To fully understand the meaning of this term a knowledge of the normal electrical reactions is necessary.

The normal formulæ for the production of muscular contraction in the physiological state are as follows, the strength of the current being barely capable of causing fair contractions:—

First. The most effective contractions are produced by the cathode (negative) pole on closing the circuit.

Second. The second most effective are produced by the anode (positive) pole on closing the circuit.

Third. The next most effective is by the anode pole on opening the circuit.

Fourth. Cathode pole contractions on opening circuit are rarely seen in the physiological state.

The "reactions of degeneration" are shown by any reversal of the regular formulæ, to wit: if the *anodal* closure shows stronger contractions than *cathodal* closure; still greater degeneration is shown if *anodal opening* contractions are stronger than either of the above; and most complete degeneration is shown by the complete reversal of the normal formulæ as shown by distinct *cathodal* opening contractions,

Sequelæ. Amongst the deformities resulting from the paralysis are the different forms of talipes.

Talipes equinus, the result of paralysis of the antero-external muscular group of the leg.

Equino-varus, the result of paralysis of the antero-external muscular group of the leg, together with the adductors of the foot.

Talipes calcaneus, the result of paralysis of the muscles of the calf of the leg.

Talipes cavus—"pes cavus"—characterized by the hollowing of the sole of the foot, with prominence of the instep, the result of paralysis of the calf muscles with contraction of the long flexor of the toe or the long peroneus—the foot flexors.

Diagnosis. The recognition of acute poliomyelitis is not always possible at the onset or during its early days, as localized paralyses are difficult of detection in children, but immobility of one leg or arm in children with febrile symptoms or following convulsions is always an indication of poliomyelitis. After the initial stage has passed, the presence of paralysis, wasting, presence of R. D. (reactions of degeneration), loss of reflexes and the absence of anæsthesia, render the diagnosis very easy.

Hemiplegia from acute cerebral affections in children can be distinguished from infantile paralysis by the disorders of intelligence and the special senses, and the perseverance of the normal electro-contractility.

Paralysis of myelitis occurs in older persons, and is associated with disturbances of the genito-urinary organs and bedsores.

Pseudo-muscular hypertrophy, with paralysis, begins gradually, becoming progressively worse with increase in the size of the limbs.

Prognosis. More or less paralysis with muscular wasting always results, although there is no doubt that the extent can be greatly lessened by early recognition and treatment.

Treatment. The diagnosis during the initial fever is impossible, so that its treatment is symptomatic. On the appearance of the paralysis, complete rest, hot spinal douche, mild galvanism, and internally, quinina, belladonna, ergota, and potassii iodidum.

With the improvement that follows the above measures, use internally, tinctura nucis vomicæ, mj-iij t. d., or hypodermic injections of strychninæ sulphas, gr. $\frac{1}{60}$ - $\frac{1}{100}$ twice a week, and faradism to the paralyzed muscles.

CHRONIC PROGRESSIVE BULBAR PARALYSIS.

Synonyms. Glosso-labio-laryngeal paralysis; bulbar paralysis. Definition. A chronic degenerative affection of certain nuclei of the medulla oblongata; characterized by a slowly progressive bilateral paralysis of the tongue, lips, palate, pharynx and larynx, with atrophy of the tongue and lips.

Causes. Obscure. Rare before the fortieth year. Among many others may be named cold, rheumatism, gout, syphilis and injuries about the neck

Pathological Anatomy. "Degenerative atrophy of the gray nuclei in the floor of the fourth ventricle; with atrophy and gray discoloration of the nerve roots from the medulla, especially of the facial and hypoglossal nerves." "Atrophy and disappearance of the motor ganglion cells is always to be noted. It may be the sole lesion." "The nerves going to the muscles exhibit sclerosis of the neuri-

"The nerves going to the muscles exhibit sclerosis of the neurilemma, and the degenerative atrophy is found in the nerve roots coming from the bulb."

Symptoms. The disease begins insidiously. There is first noticed some difficulty in articulation, from want of precision in movements of the tongue, particularly in the use of the lingual consonants, l, n, r, and t, which increases until that organ is completely paralyzed. The paralysis gradually invades the soft palate and pharyngeal muscles, causing difficulty in deglutition, of the orbicularis oris preventing closure of the lips, of the laryngeal muscles interfering with articulation. With the increasing loss of power in the tongue and lips is also a gradual atrophy of these muscles. When the disease is fully developed the condition of the patient is most pitiable, indeed; articulation is impaired or impossible, deglutition interfered with, the lips remaining apart allowing the saliva to dribble from the mouth, and liquids to return through the nose if attempts are made to swallow them. As the malady progresses, the pneumogastric nucleus becomes involved, resulting in loss of voice, difficulty of respiration and cardiac irregularity. The general health gradually suffers from insufficient nutrition and imperfect respiration, although the mind is clear until the end. The "reactions of degeneration" are present.

Besides the chronic bulbar paralysis, there are two acute forms which give the same symptoms as the chronic cases, only they develop suddenly, one, the result of hemorrhage into the medulla, which at the onset has vertigo, vomiting, loss of power in the limbs and slight sensory disturbances, all of which disappear, leaving the glosso-labiolaryngeal paralysis; the second form comes suddenly, with fever, vomiting and loss of power in the limbs soon disappearing, leaving the characteristic bulbar symptoms; this variety is inflammatory and closely allied to acute poliomyelitis.

Diagnosis. It can hardly be confounded with any other malady.

Prognosis. Unfavorable. The duration is from one to five years. Treatment. Entirely symptomatic. "Galvanism is the most promising remedy. Stabile applications, the electrodes on the mastoid processes, and in the opposite direction, galvanization of the sympathetic, and applications to the lips, tongue and fauces, should be persistently used" (Bartholow).

PROGRESSIVE MUSCULAR ATROPHY.

Synonyms. Wasting palsy; chronic spinal muscular atrophy; chronic poliomyelitis; amyotrophic lateral sclerosis.

Definition. A slowly, gradual progressive wasting and atrophy of certain groups of muscles, with symptoms varying in accordance with the variations in the pathological anatomy.

Causes. Most frequent in males between twenty-five and fifty years of age, and in many instances is hereditary. A predisposing cause seems to exist in those who habitually use one set of muscles (muscular strain). Exposure to cold and damp; lead; syphilis; injuries to the spinal column. Following such acute diseases as diphtheria, measles, acute rheumatism, typhoid and typhus fevers.

Pathological Anatomy. Two theories as to the origin of the pathological changes are held: one that the initial lesion is in the cord (Charcot), the other in the muscular interstitial connective tissue (Friedreich).

The morbid alterations are of two groups—spinal and muscular.

The spinal changes consist in the atrophy and degeneration of the anterior columns, wasting and disappearance of the multipolar ganglion-cells of the anterior horns, with hyperplasia of the neuroglia; rarely the hyperplasia extends to the lateral columns, (amyotrophic lateral sclerosis); also wasting, atrophy and degeneration of the anterior nerve roots.

The muscular changes consist of a progressive wasting of the muscular tissue, with increase of the interstitial connective tissue. "The final result is, that the muscle is converted into a mere fibrous band with numerous fat-cells, the development of this latter material taking place outside of the muscular elements and in the newly-formed connective tissue" (Bartholow).

Symptoms. The invasion is gradual, the disease having been

in progress some weeks or months before the patient is aware of its

Wasting begins usually in the hand, the first dorsal interosseus being the first to be attacked, then the muscles of the thenar and hypothenar eminence, then the deltoid, and so on from muscular group to group. Often, however, the extension is very erratic in its course, jumping from one group to another at some distance.

In the immense majority of cases the disease is permanently limited to one or a few groups of muscles in the upper, or more rarely in the lower extremities. The only muscles not yet known to be attacked are those of mastication and those that move the eye-ball (Roberts).

Fibrillary contraction is an early symptom, continuing more or less marked so long as any muscular fibres remain. It consists of wave-like movements of the muscles, excited automatically, by draughts of air or percussion. Co-incident with the wasting is loss of power, disorders of sensation, coolness of the surface, and pallor of the surface.

The natural roundness and contour of the body and limbs are changed, the bones standing out in unaccustomed distinctness, giving the individual the appearance of a skeleton clothed in skin. The hand is frequently the seat of a very singular deformity—the "claw-shaped" hand.

The *electro-contractility* is preserved so long as muscular fibres remain.

Diagnosis. When wasting palsy is fully developed its diagnosis is a simple matter. In its early stages a doubt may exist, but attention to the history, symptoms and progress will determine the question.

Syringo-myelia often begins with muscular atrophy as a marked symptom, and may be confounded with wasting palsy, the chief points of distinction between which are, the loss of power of perceiving heat, or, often, to distinguish between heat and cold, and the appearance of trophic changes, such as a dusky or purplish hue of the hands, with a uniform thickness resembling myxcedema, the development of blebs and ulcers, and changes in the nails. Arthropathies are sometimes met with.

Prognosis. Very unfavorable, although the danger to life is often very remote. The disease may be arrested and remain stationary for years.

Treatment. Internal medication seems to have no effect on the malady, although if mineral poisoning be suspected, potassii iodidum should be used, and if syphilis be suspected a course of potassii iodidum, and hydrargyrum, should be administered. Arsenicum, strychninæ sulphas, and oleum morrhuæ, with a generous diet, are amongst the remedies indicated.

If the disease is the result of overworking any set of muscles, these must be allowed a rest.

"The most effective remedy in wasting palsy is, undoubtedly, galvanism. Numerous observations attest its value when applied locally to the affected muscles" (Roberts).

I have seen improvement from the *faradic* current to the affected muscles, the strength being simply sufficient to produce contractions.

Massage is a valuable adjuvant to the electrical treatment, as are hot sponging and rubbing along the spine.

Prof. Bartholow "has apparently effected great improvement in a case, confined as yet to the left upper extremity, by the injection of glycerin solution into the wasting muscles."

SPINAL SCLEROSES.

Synonym. Duchenne's disease.

Definition. A myelitis; an increase in the connective tissue of the spinal cord, with atrophy of the nerve structure proper.

Varieties. I. Lateral sclerosis; II. Posterior sclerosis, or locomotor ataxia; III. Ataxic paraplegia; IV. Cerebro-spinal sclerosis.

Causes. Generally a hereditary neuropathic diathesis; syphilis; alcoholism; mineral poisons; shocks or injuries to the cord; exposure to cold and wet; mostly occurring between the ages of thirty-five and fifty-five; males more liable than females. It is said that railroad enginemen and firemen as well as conductors and other trainmen, suffer from this and other spinal diseases by reason of the continual concussion of railway travel. The freedom from the disease in the negro has been noted by Mitchell.

Pathological Anatomy. The changes in the cord are gradual in their development and follow a longitudinal instead of a transverse direction.

The form, consistency and color of the cord are altered, it being atrophied, indurated and of a grayish color.

The changes are hyperplasia of the connective tissue, with granular degeneration, atrophy and disappearance of the proper nerve elements. The nerve roots undergo the same fibroid change. The joints undergo remarkable atrophic degeneration—the arthropathies or Charcot joints, consisting of an osseous hyperplasia, the joint enlarging to an enormous extent.

PRIMARY LATERAL SCLEROSIS.

Synonyms. Antero-lateral sclerosis; spasmodic tabes dorsalis (Charcot); spastic spinal paralysis (Erb).

Definition. A degeneration of the lateral columns of the cord; characterized by paraplegia, contractures of the muscles, with exaggerated reflexes.

Pathogeny. The exact morbid condition is still a subject of discussion. The site of the lesion is the lateral white columns, in some cases extending to the anterior horn, and involving the whole length of the cord. The changes consist in an interstitial hyperplasia of the connective tissue, and an atrophy of the nerve elements.

Symptoms. The onset of the disease is very gradual, with increasing feeling of heaviness and weakness in the limbs, progressing to a complete paraplegia. There is also jerking and twitching with cramps and stiffness of the muscles of the paretic limbs. The spasms of the legs gradually increase in extent as the power lessens, until at last the legs, whenever extended, pass into a condition of strong extensor spasm, rigidly fixing them to the pelvis, so that the patient lies rigid, if one leg is lifted from the couch by the observer, the other leg is moved also. The spasm may be such that the knee cannot be passively flexed by any force that can be applied to it until the spasm has become less. When flexed the limb is comparatively supple: but if it is then extended, the spasm instantly returns, making the limb rigid, and often completing the extension, just as the blade of a knife opens out under the influence of its spring, "clasp-knife rigidity." Occasionally there occur brief flexor spasms, drawing the legs up.

The knee-jerk is greatly exaggerated, and there can also be developed rectus-clonus and ankle-clonus.

The spastic gait is characteristic, termed by Hammond "the waddle;" the legs drag behind and are moved forward as a rigid whole,

the toes catching against the ground, the patient showing a tendency to fall forward.

Sensation is unaffected. As the morbid process extends upward the superior extremities suffer in the same manner as those of the lower.

Electro-contractility early impaired and gradually declining until abolished.

Diagnosis. The gradual development of weakness in the legs, excess of myotatic irritability and spasms with developing spastic gait render the diagnosis clear. If the symptoms develop suddenly or acutely, the morbid condition is not of the degenerative variety.

Prognosis. Complete recovery rare. If the condition is early recognized its progress may be held in check for a long time.

Treatment. Rest of the first importance. Every means to promote the general health. If the result of lues or mineral poisons, increasing doses of potassii iodidum, or aurii et sodii chloridum. Argenti nitras, or oxidum, often retards the hyperplasia of connective tissue. Benefit may sometimes follow the use of a weak galvanic current, but as a rule electricity is disappointing in central diseases.

LOCOMOTOR ATAXIA.

Synonyms. Posterior spinal sclerosis; tabes dorsalis.

Definition. A chronic degeneration of the posterior columns of the spinal cord and the posterior nerve roots, characterized by loss of co-ordination, neuralgic pains in the limbs, loss of sensation and reflexes, and visceral and trophic changes.

Pathogeny. "A progressive destructive process which has a selective influence on certain tracts in the posterior columns with their roots and ganglia and to a less extent on the peripheral nerves, particularly the optic. The nerve fibres of the cord are first involved. Their destruction is not a simple wasting, but is accompanied with evidence of irritation such as swelling of axis cylinders and, secondarily, proliferation of connective tissue and slight congestion" (Dana).

Symptoms. Locomotor ataxia may be divided into three periods: I, disturbances of sensation; 2, loss of coördinating power; 3 paralysis.

The onset of the disease is gradual, by sharp, darting, electric-like

pains in the lower limbs, with disorders of the gastro-intestinal and genito-urinary tracts. Associated with the pains is a loss of sensation in the feet, the patient being unable to distinguish between hard and soft substances in walking, and, if the upper portion of the spinal cord be affected, is unable to coördinate the muscles of the fingers sufficiently to button his clothing. A sensation of formication over the surface, especially over the lower limbs, and about the waist, the knee and the ankle, is present; there is nearly always a feeling of constriction about the trunk—the girdle.

Loss of coördination or ataxia, the subject being unable to walk upon a straight line with his eyes closed, and with difficulty if his eyes are opened. Inability to preserve the erect position with the feet close together, the body swaying widely and the patient falling on standing with closed eyes,—Romberg's symptom, and as the malady progresses he throws his feet and legs in the most grotesque manner. Although the patient is unable to coördinate the muscles, their power is not lost, for, on being supported, he can kick or strike with his usual force.

The sight is early impaired, due to atrophy of the optic nerve, either double vision or inability to distinguish between different colors. Very early there is loss of pupil reflex to light, the reaction to accommodation being present—Argyll-Robertson symptom. As the disease progresses the sensation becomes more and more blunted and pain is slowly felt, in cases it being several minutes until the sticking of a pin is appreciated. A characteristic sign of the disease is the abolition of the patellar tendon-reflex—Westphal's symptom, as well as other reflexes in the lower limbs. Loss of the sensation of temperature also occurs. The electro-contractility is decreased in the affected limb. General emaciation is marked.

Either early or late in the disease occur disturbances in micturition and loss of sexual power and often desire. There also occur in a fair number of cases, painless swelling and disintegration of various joints, particularly the knee and elbow—the tabetic arthropathies, or Charcot joint.

At any period of the disease peculiar *crises*, or neuralgic attacks occur: if griping pains in stomach with vomiting—gastric crises; if renal pain or colic with disturbed urinary flow, nephralgic crises; if pain in bladder, vesical crises; if pain in rectum with hemorrhoids, rectal crises; if severe paroxysm of coughing, bronchial crises; if

constriction of throat with dyspnœa, laryngeal crises; if cardiac pain and tachycardia, cardiac crises.

Paralysis finally ends the suffering of the patient. There is generally an entire absence of cerebral phenomena.

Diagnosis. There are three pathognomonic symptoms of locomotor ataxia whose presence render the diagnosis positive, they are Westphal's symptom—absence of patellar reflex, Romberg's symptom—swaying of body and inability to maintain erect position with closed eyes, and the Argyll-Robertson symptom—loss of pupil reflex to light but reaction to accommodation retained. Another important point is the history of syphilis five to twenty years before.

Chronic myelitis is characterized by paralysis, and the course of the affections are otherwise so different that an error should not occur.

Disease of the cerebellum presents symptoms of disordered coördination, but they are the result of vertigo, and associated with headache, nausea and vomiting and neuralgic pains and eye symptoms absent.

Paraplegia is a true paralysis, while sclerosis is not. Neuralgic pain is not a symptom of paraplegia.

Multiple neuritis gives loss of power with pain but does not present the three pathognomonic symptoms mentioned above.

Prognosis. Unfavorable. Few if any recoveries are recorded, although rarely the progress has been retarded for a long time. There are some claims of recoveries of locomotor ataxia in the early stage, but that a cure of a genuine case, extending to the second stage, is ever effected, seems very questionable.

Treatment. In the management of locomotor ataxia, *rest*, as near absolute as possible, is of the first importance,—it will be all the more effective if it be in bed, for a period of several months.

Following the suggestion of Erb, use may be made of *cold along* the spine, in the shape of cold sponging, cold spinal pack or short application of the cold douche to the spine. The galvanic continuous current along the spinal column is warmly advocated, with faradism to the wasting muscles.

Potassii iodidum, or hydrargyri chloridum corrosivum, in full doses, or aurii et sodii chloridum, gr. $\frac{1}{20}$, three times a day, often remarkably retard the progress of the affection. The best results are obtained, however, from argenti nitras, gr. $\frac{1}{4}$ - $\frac{1}{2}$, or oxidum, gr. $\frac{1}{2}$, three times a day, withholding it at intervals of a few weeks, to prevent discoloration of the skin (argyria).

Temporary success at least, seems to have followed, in some cases of locomotor ataxia in the second stage, from the "suspension treatment" as recommended by Charcot. The treatment consists of the suspension of the patient during a period varying from one to four minutes, by means of the Sayre apparatus for applying the plaster jacket in spinal deformities.

The severe and sharp pains require treatment, at first giving preference to any of the substitutes of opium, but finally *opium* itself will have to be resorted to; the actual cautery applied to the back once a month is said to relieve the pains.

The diet should be of a nutritious, easily-assimilated character. Nutrition can also be promoted by the use of *oleum morrhuæ*, and, syrupus calcii lacto-phosphatis.

ATAXIC PARAPLEGIA.

Synonyms. Combined lateral and posterior sclerosis; anterolateral sclerosis.

Definition. A chronic degeneration of the lateral pyramidal tracts and of the posterior columns of the spinal cord; characterized by gradual developing paraplegia, with ataxia, and spasms of the limbs.

Causes. The causes are not so well determined as in other varieties of spinal sclerosis.

Pathogeny. A sclerosis of the lateral and posterior columns of the spinal cord. It is to be noted that the posterior columns show the morbid changes higher up than in locomotor ataxia—the dorsal rather than the lumbar regions, and that the root-zone of the postero-external column is much less involved. Nor do the lateral tracts show the same degree of involvement as in spastic paraplegia.

Symptoms. The onset is slow and gradual, with loss of power in the lower extremities. The muscles involved are particularly the flexors of the thigh and knee. One leg may be weaker than the other. There is also ataxia, the patient being unsteady when standing with feet together and he tends to fall if the eyes are at the same time closed. Spasms of the lower extremity gradually develop and finally become as marked as in spastic paraplegia. The kneejerk reflex is increased, quick and extensive, and rectus and ankle clonus can be developed. The sexual power is early lost. Inconti-

nence of urine is frequent. Sensation is unimpaired and neuralgic pains are absent, as are eye symptoms.

Diagnosis. The conditions ataxic paraplegia is most liable to be mistaken for, are locomotor ataxia and spastic paraplegia. The presence of knee-jerk and loss of power in lower extremities are of value in discriminating from locomotor ataxia. Spastic paraplegia is not associated with ataxia, indeed ataxic paraplegia is spastic paraplegia plus inco-ordination.

Prognosis. As a rule unfavorable.

Treatment. The same plan of treatment may be tried as recommended for lateral or posterior sclerosis.

CEREBRO-SPINAL SCLEROSIS.

Synonyms. Multiple sclerosis of the brain and cord; cerebral sclerosis; spinal sclerosis; disseminated sclerosis (Charcot).

Definition. A degenerative disease of the brain and spinal cord; characterized by pains in the back, disorders of sensation, loss of coordination, tremor on motion, scanning speech, and some mental impairment.

Pathogeny. The disease consists of the development of patches of grayish, translucent, tough nodules, varying in size from a minute microscopical object up to the size of a walnut, varying in number and widely distributed in the white matter of the hemispheres, ventricles, optic thalamus, corpus striatum, peduncles, pons and cerebellum, while in the cord they are found in both the white and gray matter and in the columns. The deposits are also found in the nerve roots and nerve trunks. The nodules are composed of the neuroglia, much altered, and a newly-formed connective tissue. The result of the growth of the nodules is pressure upon the nerve structure, ending in its degeneration.

Symptoms. Charcot divides this disseminated sclerosis into three varieties, depending upon the site of the marked changes, as the brain, the cord or a combination of the two. The latter variety is the more common.

Rarely, the malady is ushered in with apoplectiform symptoms, but generally the onset is insidious, with pains more or less severe in the limbs and back, which are attributed by the patient to rheumatism. Also a feeling of formication, itching and burning in the limbs. Loss

of co-ordination of the hands in writing, or the feet in walking, or a jerky co-ordination, followed after a time by paresis, more or less general, with contracture of the muscles. Voluntary movements of the paretic limbs develop a tremor—the shaking tremor—which subsides when the limbs are at rest—intention tremor, with shaking of head. An early and frequent condition is nystagmus. The loss of co-ordination, with tremor and with contractures of the muscles of the legs, has given rise to the "waddle," or "hop" gait when walking. There are also present headache, vertigo, mental impairment with an unnatural contentment of the feelings and with the surroundings, a scanning or slurring speech, disorders of vision and hearing, sexual disturbances, vesical disorders, gastric and other crises, and often the development of bed-sores.

Knee-jerk and muscular reflexes are exaggerated.

The disease is progressive, the symptoms developing as the various nerve tracts are invaded.

Duration. Ranges from a year to twenty years, an average being five or ten years.

Diagnosis. Paralysis agitans may be mistaken for disseminated sclerosis. The chief points in the diagnosis are the presence in paralysis agitans of the fine tremor continually without shaking of the head, with a peculiar flexion and rigidity of the hand, while in cerebrospinal sclerosis the tremor is produced only on movement of the muscle, and is associated with shaking of the head. Paralysis agitans, a disease of middle life, sclerosis under forty years. Changes in the voice, speech and vision are present in cerebro-spinal sclerosis, but absent in paralysis agitans.

Tumor of the pons or crus is accompanied with wild, jerky incoordination closely resembling disseminated sclerosis, but tumor also has headache, optic neuritis, local spasm and local paralysis.

General paralysis of the insane and disseminated sclerosis are frequently confounded, as are locomotor ataxia, and primary lateral sclerosis.

Prognosis. Unfavorable. The disease slowly but steadily progresses, chronic nephritis or tuberculosis, frequently developing and causing death.

Treatment. There is no drug having the power to cure sclerosis. Syphilis has been the cause of the vast majority, if not all the cases observed by the writer, and *potassii iodidum*, in large doses, or the

following, has seemed in a few instances to hold the disease in check for a time:—

R. Hydrargyri chloridi corros., gr. j
Liq. arsenici chloridi, f z j
Inf. gentian, ad f z iij. M.
SIG.—Teaspoonful three times daily, in water.

DISEASES OF THE NERVES.

SIMPLE NEURITIS.

Definition. An inflammation of the nerve trunks; characterized by pain and paresis of the parts supplied by the affected nerve trunk.

Causes. Wounds and injuries or compression of nerves; cold and damp; syphilis (?), lead.

Pathological Anatomy. Hyperæmia, followed by exudation into the nerve sheath and connective tissue, "which becomes softened and ultimately breaks down into a diffluent mass." Migration of white corpuscles takes place into the neurilemma. Recovery may occur before destruction of the nerve elements is produced, absorption of the exudation occurring. "It is important to note that when inflammation occurs in a nerve it may extend from the point first diseased upward (neuritis ascendens), or downward (neuritis descendens)."

Symptoms. The onset may be accompanied with febrile reaction. The most decided symptom is pain along the course of the nerve trunk and its peripheral distribution, of a burning, tingling, tearing, intense character, increased by pressure or motion. If the affected nerve be a mixed one—sensory and motor—spasmodic contractions and muscular cramps occur, followed by impaired motion, terminating in paresis of the muscles innervated by the affected trunk.

If the inflammation proceed to destruction of the nerve trunk, wasting and degeneration of the muscular tissue ensues. Various trophic

changes also occur, such as cutaneous eruptions, and clubbing of the nails. The *electro-contractility* is impaired or lost.

Diagnosis. Myalgia or muscular pain is not associated with paralysis, nor does the pain follow the course of a nerve trunk.

Neuralgia has the pain, but as a rule, not the tenderness of neuritis.

Prognosis. Generally favorable, with proper treatment.

Treatment. Repeated blistering along the course of the nerve, with full doses of potassii iodidum, are usually successful. Sodii salicylas, phenacetin, and antifebrin, are each of utility.

As the more acute symptoms subside, the use of *galvanism* or a feeble, slowly interrupted *faradic* current, restores the disordered function of nerve and muscle.

MULTIPLE NEURITIS.

Synonyms. Polyneuritis; peripheral neuritis; disseminated neuritis; degenerative neuritis; pseudo-tabes; alcoholic paralysis; beri-beri (Brazil and India); kakké (Japan).

Definition. A parenchymatous inflammation of a number of symmetrical nerves, simultaneously or in rapid succession; characterized by pain, numbness, loss of power, or ataxia, with muscular atrophy. Mental symptoms are often associated.

Causes. Alcoholism; syphilis; malaria; lead, arsenic or silver; following diphtheria, typhoid fever, and rheumatism.

Beri-beri and kakké are epidemic varieties of multiple neuritis and the result of a special poison.

The probability is that the various causes named develop in the blood a poison, having a particular susceptibility or "selective action" for nerve fibres.

Pathological Anatomy. The affection is generally bilateral and symmetrical. An important characteristic is its peripheral distribution, the inflammation being most intense at the extremities of the nerves, lessening progressively toward the centre, usually terminating before the nerve roots are reached. The inflammatory process affects the nerve-fibres primarily and the sheath and connective tissue secondarily—a parenchymatous inflammation. The affected muscles are paler and smaller than normal, the fibres reduced in size and undergoing granular changes.

Symptoms. All plans yet suggested for classifying the varieties

of multiple neuritis are imperfect. The onset may be sudden, even overwhelming, causing rapid death, but is usually sub-acute or chronic in its course, the symptoms being wide-spread in proportion to the acuteness, intensity and cause of the malady. The symptoms may be described under three forms—a motor, a sensory and an ataxic form.

The *motor* form shows motor weakness, chiefly involving the flexors of the ankles, the extensors of the toes, and the extensors of the wrist and fingers in the forearms. Inflammation of the anterior tibial or peroneal nerve in the leg, and the radial branch of the musculospiral in the arm, resulting in the double "wrist-drop" and "footdrop" so characteristic of this disease. Any nerves of the body may be affected, the symptoms varying with the particular nerves.

The sensory form shows pains, tenderness, tingling and numbness with loss of cutaneous sensibility.

The ataxic form shows inco-ordination with or without sensory disturbances, but with loss of the muscular sense.

The forms may all be associated, in greater or less extent, in any one case.

Muscular atrophy begins early and progresses with the disease.

The knee-jerk is feeble or absent. The electro-contractility is feeble or lost.

In alcoholic cases, there may be delirium, mania and delusions, associated with tremors.

Trophic changes may occur in the nails, hair and skin. The characteristic glossy condition of the skin with some cedema, is due to involvement of the vaso-motor nerves. Rarely the vagus, optic and laryngeal nerves are involved.

The disease may be ushered in with fever, 101° F.-103° F., rapid, feeble pulse, headache, nausea, vomiting with delirium or confusion.

The alcoholic variety affects chiefly all the limbs; the malarial, the legs; diphtheria, the pharyngeal and motors of the eye; rheumatic, the face, and lead, the arms.

Diagnosis. In no disease is an early diagnosis so important from a therapeutical standpoint. Early treatment may prevent months of suffering and idleness.

Since the symptoms of this widespread affection have been properly separated from diseases of the spinal cord, with which they were formerly always associated, the diagnosis is very readily determined.

Prognosis. As a rule favorable if early and proper treatment be instituted.

Treatment. Rest is of the greatest importance; the more thoroughly this is carried out the better will be the results.

Removal of the cause is an important indication. Warmth to the affected parts by hot baths, and keeping the parts wrapped in cottonwool.

There is no specific drug for polyneuritis. For alcoholic cases, use strychninæ sulphas; for malarial cases, quininæ sulphas; for diphtheritic cases, tinctura ferri chloridi; for rheumatic cases, sodii salicylas, salol, or phenacetin; for syphilitic cases hydrargyrum or potassii iodidum, and in all varieties tonics with a generous nutritious diet.

Pain should be relieved with either antifebrin, or morphinæ sulphas, by the hypodermic method. As convalescence begins, moderate exercise and mild galvanism.

NEURALGIA.

Definition. A disease of the nervous system, manifesting itself by sudden pain of a sharp and darting character, mostly unilateral, following the course of the sensory nerves.

Varieties. I. Neuralgia of the fifth nerve; II. Cervico-occipital neuralgia; III. Cervico-brachial neuralgia; IV. Dorso-intercostal neuralgia; V. Lumbo-abdominal neuralgia; VI. Sciatica.

Causes. Hereditary; anæmia; malaria; syphilis; metallic poisons; anxiety; mental exertion; exposure to cold and damp; injuries of a nerve trunk.

Pathological Anatomy. The old axiom of neuralgia being "the cry of the nerves for pure blood" is perhaps only part of the truth. The changes in the nerve trunks or centres have not as yet been determined. A fair number of cases present the changes of neuritis.

NEURALGIA OF THE FIFTH NERVE.

Synonyms. Tic-douloureux; Fothergill's disease.

Symptoms. Paroxysmal pain, of a sharp, darting, stabbing character, most common at points along the course of the supra- and infra-orbital branches of the fifth nerve of the left side, attended with increased lacrymation. When of any duration, nutritive changes are observed in the nervous distribution, to wit: adema along the course

of the nerve, gray eyebrows and convulsive twitches of the muscles, termed "tic douloureux," tenderness at the infra- and supra-orbital foramina, as well as along the course of the nerve distribution.

CERVICO-OCCIPITAL NEURALGIA.

Symptoms. Paroxysmal pain, of a sharp and lancinating, or deep, heavy, tensive character, along the course of the occipital nerve upon one or both sides, extending from the vertex, and on the neck as far down as the clavicle, and upward and forward to the cheek. May be associated with hyperasthesia of the skin, and with cramps in the cervical muscles, and with attacks of herpes. A sensation of cracking at the nape of the neck is an annoying symptom in many cases.

CERVICO-BRACHIAL NEURALGIA.

Symptoms. Paroxysmal pain, of a severe, boring, burning or tensive character, with sensations of numbness and weakness of the arm, hand, shoulder, scapula and mamma, with tenderness along the cervical plexus. Edema of the arm and other parts along the distribution of the cervical plexus occur if the neuralgia be of long duration, the result of nutritive changes, the limb at times becoming pale, the skin glossy, dry and harsh.

DORSO-INTERCOSTAL NEURALGIA.

Symptoms. Paroxysmal pain of a sharp and lancinating character, along the fifth and sixth intercostal spaces, often associated with the development of herpes, the so-called herpes zoster, or "shingles."

Tenderness at the points where the nerves emerge from the intervertebral foramina at the sides of the chest and at points in front.

LUMBO-ABDOMINAL NEURALGIA.

Symptoms. Paroxysmal pain of a sharp and lancinating, at times heavy and dull character, following the course of the ileo-hypogastric nerve, ileo-inguinal and external spermatic nerve, supplying the integument of the hip, the inner side of the thigh, the scrotum and labium.

SCIATICA.

Definition. A neuritis. Pain following the course of the sciatic nerve. The sacral plexus is made up of the fourth and fifth lumbar and the first two pairs of sacral nerves.

Symptoms. Sciatica usually follows an attack of lumbago, the pain becoming fixed in the sciatic nerve; at times it is a true neuritis. *The pain is sharp*, tearing, shooting or lancinating in character, increased upon motion, shooting along the course of the nerve into the hip, inner side of the thigh, calf of the leg, ankle and heel, at one or all of these points, in paroxysms lasting from a few hours to twenty-four hours or longer. The tactile sensation in the foot and motility in the limbs are impaired, and if of long duration, wasting of the limb occurs

Diagnosis. *Rheumatism*, so-called, is the only condition likely to be confounded with neuralgia.

The history of the attack, the character of the pain, with its localized spot of tenderness, should prevent such an error.

Prognosis. If promptly and properly treated, unless the result of pressure of an exostosis, aneurism or other tumor, favorable.

Treatment. Rest; easily assimilated but nutritious diet; removal of the cause, if possible. If anæmic, ferrum and arsenicum. If rheumatic, alkalies, and sodii salicylas. If syphilitic or the result of metallic poisons, potassii iodidum. If malarial, quinina.

For an attack, *morphina* and *atropina*, hypodermically, affords the most prompt and ready relief.

Success usually follows the use of the well-known "Gross (Prof. S. D.) neuralgic pill:"—

R.	Quininæ sulphat., .				,				gr. ij	
	Morphinæ sulphat.,								gr. 20	
	Strychninæ sulphat.	9 .						,	gr. $\frac{1}{20}$	
	Acidi arseniosi,								gr. $\frac{1}{20}$	
	Extracti aconiti,								gr. ½.	M.
Ft	. pil. No. 1.									

Sig.—One every one, two or three hours.

Few attacks of trigeminal neuralgia will resist the following powerful prescription:—

R.	Aconitinæ (Duquesnel), .			gr. $\frac{1}{10}$	
	Glycerini,				
	Alcoholis,	٠	āā	· • • • • • • • • • • • • • • • • • • •	3.6
	Aquæ menth. pip.,				М.
SIG.	—Teaspoonful, repeated from	n	four to eight	times daily,	carefully

Facial neuralgia is often wonderfully benefited by the internal administration of ext. gelsemii fld., gtt. iij-v, every three or four hours, until its physiological effects are produced. Excellent results often follow the administration of Moussette's pills (aconitine and quinine).

For sciatica, antipyrin, gr. xx, repeated two or three times daily, has given relief, as has phenacetin, or antifebrin. The deep injection of chloroformum, is recommended by Bartholow. A spray of chloride of methyl along the course of the nerve for a few moments, watching the skin, will relieve the distressing pain. Rarely full doses of potassii iodidum with a blister along the course of the nerve gives relief.

All forms of neuralgia are more or less benefited by-

R .	Quininæ sulph.,							·						gr. iij

In	pill, every four of	or i	ive	ho	urs	6.									

FACIAL PARALYSIS.

Synonym. Bell's palsy.

Definition. An acute paralysis of the seventh cranial—the facial nerve, the great motor nerve of the muscles of the face—the *nerve* of expression.

Causes. Exposure to a current of cold air against the side of the face—over the *pes anserinus*—is the most frequent cause. Also due to injury or disease of the middle ear. Syphilis.

Symptoms. The facial nerve supplies the muscles of the face, the muscles of the external ear, also the stylo-hyoid, posterior belly of the digastric, the platysma, one muscle of the middle ear, the stapedius, and one palate muscle, the levator palati; by means of the chorda tympani branch it controls the secretion of the parotid and submaxillary glands, and, possibly, the sense of taste. It also furnishes motor power to the azygos uvulæ, the tensor tympani and the tensor palati muscles.

The onset is usually sudden, with tingling of the lips and tongue, and upon looking into the mirror the patient is surprised by the perfectly blank, motionless side of the face; the corner of the mouth is depressed, the eyelids open, the face drawn toward the well side, and the patient is unable to expectorate, whistle or swallow.

Any of the muscles innervated by the nerve may participate in the paresis.

The electro-contractility is feeble or lost. The reflexes are abolished.

Diagnosis. Paralysis of the muscles of the face occurs in hemiplegia; the points of differentiation are the presence of cerebral symptoms and the normal reflex excitability.

Facial palsy with otorrhoea, imperfect hearing, obliquity of the uvula and loss of taste, determine its origin within the aquæductus

Fallopii.

It is due to peripheral neuritis if the taste be normal and the uvula straight.

If other nerves are also involved the origin is central.

Prognosis. Favorable.

Treatment. If the result of cold and damp, diaphoresis with *pilocarpus*, or diuresis with *potassii acetas*, vel iodidum, and blisters in front of the ear, and the use of galvanism to the affected muscles.

GENERAL OR NUTRITIONAL DISEASES.

CHOREA.

Synonyms. St. Vitus's dance; insanity of the muscles.

Definitions. A functional (?) disorder of the nervous system; characterized by irregular spasmodic movements of groups of muscles, with muscular weakness, more or less approaching paralysis of the affected parts.

Causes. Essentially a disease of childhood; hereditary; reflex, from dentition, worms, masturbation or fright; probably the result of rheumatism in many cases.

Pathological Anatomy. As yet there has been no constant anatomical lesion discovered, the theory of emboli having, however, many advocates.

Symptoms. The onset is usually gradual, the child seemingly grimacing or jerking the arm or hand, as if in imitation, followed soon by decided, *irregular jactitations* of the muscles of the face (histrionic

spasm), of the eyelids (blepharospasm), eyeballs (nystagmus), and the shoulder, arm and hand, finally extending to the lower extremities, interfering with *motility*; in severe cases, inability of self-feeding or of holding anything in the hands. The *speech* is often unintelligible, the tongue constantly moving in an irregular manner.

The heart's action is tumultuous and irregular, associated often with a soft, blowing, systolic murmur, most distinct at the base. The muscles are usually quiet during sleep, although this is not always the case. The mind is somewhat blunted, the temper irritable, the memory impaired. If the irregular muscular movements are confined to one side of the body, it is termed hemi-chorea.

Diagnosis. Chorea was confounded with epilepsy until the points of distinction were pointed out by Sydenham.

Paralysis agitans has general muscular tremor, beginning in one limb, gradually progressing, uninfluenced by treatment; a disease of the elderly.

Post-hemiplegic chorea is the choreic movement of a paralyzed limb. Prognosis. The vast majority of cases recover, but relapses are very frequent.

Treatment. Remove the cause, if possible. Easily assimilated diet. Many cases improve rapidly by confinement to bed in a darkened room. If the muscular movements interfere with sleep, *morphina* or *chloral* are indicated. Regulate the secretions.

Arsenicum is the most reliable remedy yet introduced for the treatment of chorea. It should be pushed to its first physiological effects, then gradually reducing the dose until all symptoms disappear. The form of the remedy best adapted for administration in this disease is liquor potassii arsenitis, gtt. v, increased to gtt. x, or even gtt. xv, three times a day. Extractum cimicifugæ fluidum, m_{xx-f} 3j, t. d., is serviceable, especially in cases following a rheumatic attack. Cases resisting the arsenicum treatment may succumb to hyoscyamine, gr. $\frac{1}{200}$ $\frac{1}{100}$, three times daily. A patient of mine, aged 16 years, who resisted all the remedies mentioned, was promptly cured by antipyrin, gr. x, four times daily. This same case in a former attack was arrested by morphinæ sulphas, gr. ¼, four times daily, but this latter remedy failed in the attack controlled by the antipyrin. If anæmia be present, combine or alternate arsenicum with ferrum. Wood recommends quinina.

EPILEPSY.

Definition. A chronic disease, of which the characteristic symptoms are a sudden loss of consciousness, attended with more or less general convulsions.

Causes. Heredity; rarely, worry, anxiety, depression, or fright. Pressure from a tumor at the periphery, or thickening of the membranes of the brain, causing pressure; dyspepsia (?); syphilis; uterine diseases.

Pathological Anatomy. There are no constant anatomical lesions, as yet, associated with essential epilepsy.

In "Jacksonian," "cortical," or "partial epilepsy," however, the "motor cortex" is irritated by disease and there occur tonic and clonic spasms of the same character as in general epilepsy, confined to a single arm, or an arm and half the face together, or may be the entire half of the body. These epileptiform attacks furnish precise data as to the locality of the lesion; spasms affecting the distribution of the facial nerve point to the lower third of the central convolution; of the arm, the middle third of central convolution; of the lower extremity, the upper third of the central convolution.

Varieties. I. Epilepsia gravior, le grand mal; II. Epilepsia mitior, le petit mal.

Symptoms. Le grand mal is preceded by a more or less pronounced and curious sensation, the so-called aura epileptica.

The attack proper is sudden, the subject suddenly falling, with a peculiar cry, loss of consciousness, and pallor of the face, the body assuming a position of tetanic rigidity, succeeded after a few moments by more or less pronounced clonic convulsions, followed by a coma of several hours' duration. The subject awakens with a confused or sheepish expression, with no knowledge of what has occurred, unless he has injured himself during the attack, either by the fall, or, what is very common, has bitten his tongue during the convulsions.

Le petit mal is manifested either by attacks of vertigo, the consciousness being preserved, or by a passing absent-mindedness, either form being associated with slight convulsive phenomena, followed by slight coma or mental confusion of short duration.

The mental functions are not, as a rule, injured by attacks of epilepsy, unless they recur very frequently. Indeed, when at wide

intervals, the subject seems relieved by them, "the sudden, excessive, and rapid discharge of gray matter of some part of the brain on the muscles," the so-called "electrical storm," having cleared the cerebral atmosphere.

The great majority of epileptics suffer from chronic gastric catarrh, and have at the same time an inordinate appetite (boulimia); indeed an attack of gluttony may immediately precede a fit.

Diagnosis. *Uramic convulsions* closely resemble an epileptic attack; but the dropsy or general ædema and albuminous urine, increased temperature, of the former should guard against error.

Feigned epilepsy often misleads the most practical expert.

Jacksonian epilepsy begins as a spasm of a limb or some portion of a limb, and is confined there or may gradually extend until even a general convulsion occurs.

Prognosis. The vast majority of cases will not recover under treatment, but have the frequency and severity of the attacks greatly ameliorated, but sooner or later returning with their former severity. Cases the result of the various reflex causes usually recover when the cause is removed.

Treatment. To avert an impending attack, inhalations of *amyl nitris*, gtt. iij-v, a few whiffs of *chloroformum*, or the hypodermic injection of *morphina*.

To prevent the return of attacks, remove the cause if possible; attention to the secretions and the internal administration of potassii bromidum, in doses sufficient to abolish the faucial reflex and produce the symptoms of bromism, have great power in diminishing the severity and frequency of the attacks; better results are sometimes obtained by the combination of the various bromides. Cases in which the bromides are not serviceable are sometimes benefited by argenti nitras, belladonna, or cannabis indica, but such cases must be rare. Weak and anæmic subjects usually do better with strychnina in full doses than with potassii bromidum. If a history of syphilis can be obtained, the combination of potassii iodidum, and potassii bromidum, will effect a cure.

Whichever of the above remedies is beneficial in any particular case, the permanency of the relief can only be maintained by the continuation of the drug for at least two years after the last attack.

Gowers highly recommends the following in cases complicated with cardiac dilatation:—

R.	Potassii bromidi,													3.5
	Tinct. digitalis, .	۰				9		٠	٠	0	٠	٠	mx.	Μ.
Sig.	-Three times a day	v.	we	11	dil	lut	ed							

The following is the combination used in the insane wards of the Philadelphia Hospital:—

R.	Sodii bromidi,										
	Potassii bromidi,			ãâ					٠	Ziv	
	Liq. potassii arsenitis,				۰	٠				f 3 viss	
	Inf. gentian. comp.,		q.	. S.	ad		٠	4		f 🖁 viij.	M.
	-Tablespoonful, diluted									_	

Brown-Séquard's mixture for epilepsy is as follows:-

R.	Potassii iodidi,									٠	٠	8 part	s.
	Potassii bromidi, .				٠			٠				8 "	
	Ammonii bromidi,	0		٠			٠		٠		٠	4 "	
	Potassii bicarb., .	0	۰			۰						5 "	
	Inf. columbo,											360 "	

Sig.—One teaspoonful before meals and three desserts poonfuls on going to bed.

The diet of the epileptic must be carefully regulated, meats, tea and coffee excluded, or used in very moderate amounts. Forbid tobacco and alcohol

Much enthusiasm is reported in the important results following trephining in cases of Jacksonian epilepsy. It is to be hoped success will follow this operation, but the subject is still sub judice.

HYSTERIA.

Definition. A nutritional disorder of the nervous system, of the nature of which it is impossible to speak definitely; characterized by disturbances of the will, reason, imagination, and the emotions, as well as motor and sensory disturbances.

Causes. A morbid condition confined almost exclusively to women. Young girls, old maids, widows, and childless married women are the most frequent subjects of the disorder. The paroxysms frequently develop during the menstrual epoch. The menopause is another frequent period for its manifestation. A peculiar condition of the nervous system, either inherited or acquired, is

responsible for the phenomena of hysteria, the peculiar manifestations being excited by disturbances of either the sexual, digestive, circulatory, or nervous systems.

Hypochondriasis, a peculiar mental condition, characterized by inordinate attention on the part of the patient to some real or supposed bodily ailment or sensation, a continual introspection, as seen in males, is a condition much like the hysteria of the female.

Pathogeny. Structural alterations have thus far not been detected in cases of hysteria; it is thus a functional disturbance of the nervous system. It should, however, be borne in mind that hysterical manifestations frequently develop during the prevalence of organic diseases.

Symptoms. These will be considered under the headings of the *hysterical paroxysm*, and the *hysterical state*.

The Hysterical paroxysm or fit occurs nearly always in the presence of others, and develops gradually with sighing, meaningless laughter, causeless moaning, nonsensical talking and gesticulations, or a condition of fidgets followed with a sensation of choking, dyspnwa, and a ball in the throat—the globus hystericus. These and similar symptoms precede the fit, during which the unconsciousness is only apparent, the patient being aware of what is transpiring about her. During the paroxysm the patients may struggle violently, throwing themselves about, their thumbs turned in and their hands clenched. Again, spasmodic movements occur, varying from slight twitching in the limbs to powerful general convulsive movements, and to almost tetanic spasms.

The paroxysm ends by sighing, laughing, crying and yawning, and a sensation of exhaustion. During the attack it will be noted that the surface and face are normal, showing absence of respiratory embarrassment, the breathing varying from very quiet to spluttering and gurgling sounds, the pupils not dilated, the pulse normal, the temperature normal, and absence of foaming at the mouth and wounding of the tongue.

The Hysterical State is shown by disturbances of the *mental* and *sensory-motor* functions respectively. It may be a permanent condition or occur at intervals with greater or less severity.

Mental disturbances. The patients are emotional, erratic, excitable, impatient, and self-important, showing marked defects of will and mental power.

Sensory disturbances. This is either a condition of exaggerated sensibility or hyperæsthesia, as shown by the marked effects from the slightest irritation and the cutaneous tenderness along the spine, or a condition of anæsthesia as shown by the apparent absence or recognition of pain after severe irritation, or a perverted sensibility as shown by the feeling of tingling, numbness, and formication. Sensibility to heat or cold are often absent. There is great perversion of the special senses in many of the cases.

Charcot, referring to the ovarian hyperæsthesia of hysteria, says: "It is indicated by pain in the lower part of the abdomen, usually felt on one side, especially the left, but sometimes on both, and occupying the extreme limits of the hypogastric region. It may be extremely acute, the patient not tolerating the slightest touch; but in other cases pressure is necessary to bring it out. The ovary may be felt to be tumefied and enlarged. When the condition is unilateral, it may be accompanied with hemianæsthesia, paresis, or contracture on the same side as the ovarialgia; if it is bilateral, these phenomena also become bilateral. Pressure upon the ovary brings out certain sensations which constitute the aura hysterica, but firm and systematic compression has frequently a decisive effect upon the hysterical convulsive attack, the intensity of which it can diminish, and even the cessation of which it may sometimes determine, though it has no effect upon the permanent symptoms of hysteria."

Motor disturbances. These phenomena embrace every variety of motor disturbance, from exaggerated excitable movements to defective or complete loss of power. With the paralysis that may occur, neither nutrition nor sensation are constantly impaired. Hysterical paralysis is liable to frequent and sudden changes, the loss of power often disappearing suddenly. Aphonia, from paralysis of the laryngeal muscles, is a frequent form of paresis. Some hysterical patients refuse to even make an attempt at speech.

"A curious enlargement of the abdomen is observed sometimes, constituting the so-called *phantom tumor*. This region presents a symmetrical prominence in front, often of large size, with a constriction below the margin of the thorax and above the pubes. The enlargement is quite smooth and uniform, soft, very mobile as a whole from side to side, resonant, but variable on percussion, and not painful. Vaginal examination gives negative results, and under chloro-

form the prominence immediately subsides, returning again as the patient regains consciousness."

Among the numerous other symptoms that may develop in a hysterical patient are disturbances of digestion, circulation, respiration, and disorders of micturition and menstruation.

Among other phenomena that belong to the Hysterical state are to be mentioned Hystero-epilepsy, a condition of hysteria to which is superadded the convulsion, epileptic in form; Catalepsy, a condition in which the will seems to be cut off from certain muscles, and in whatever position the affected member is placed, it will so remain for an indefinite time. There may or may not be unconsciousness and loss of sensation; Trance, the individual lying as if dead, circulation and respiration having almost ceased; Ecstasy, a condition in which the individual pretends to see visions and acts in a most ridiculous manner.

Diagnosis. The hysterical state is so general in its manifestations that it is to be borne in mind in diagnosing all ailments occurring in women. The diagnosis is attended with great difficulty, however, and requires the display of all the skill of the clinician to prevent error.

Prognosis. Death from either a hysterical fit or the hysterical state is the rarest of events, if it ever occur. The ultimate recovery of a hysterical patient is of frequent occurrence. Marriage has cured many cases, although it can hardly be advised by the physician.

Treatment. For the hysterical fit little need be done, as a rule, unless the paroxysm is violent or prolonged, in which case ammonia valerianas, Hoffman's anodyne, or spiritus ammonia aromaticus, may be administered. Charcot recommends the making of firm pressure over the ovarian region to check hysterical fits that are of a severe character.

The management of a confirmed case of hysteria will tax the skill of the most astute physician. It is in connection with hysteria that the peculiar phenomena supposed to arise from applying different metals to the surface of the body have been noticed.

Moral and hygienic measures are of the first importance in the management of an hysterical patient. The treatment by *isolation* of hysterical patients is strongly urged by many specialists. Dr. S. Weir Mitchell has devised a plan for bedfast hysterical patients, of massage, faradization, and forced feeding, which is successful in a number of cases.

There is no fixed therapeutical treatment for hysteria, the various symptoms calling for interference as they arise. It is well, however, to avoid the use of stimulants, opiates, and chloral.

NEURASTHENIA.

Synonyms. Spinal irritation; nervous prostration; nervous exhaustion.

Definition. A debility of the nervous system, causing an inability or lessened desire to perform or attend to the various duties or occupations of the individual.

Prof. Bartholow describes it as consisting "essentially in an exaggerated susceptibility to bodily impressions and false reasoning thereon."

Causes. It may result from various chronic diseases; mental worry or emotion; overwork, as "whenever the expenditure of nerve-force is greater than the daily income, physical bankruptcy sooner or later results" (Jackson). Neurotic temperament; sexual excesses; alcohol; tobacco.

Symptoms. Nervous debility may affect any organ of the body. It is a condition of nerve-tire or exhaustion, and hence the nervous energy necessary for functional activity of any particular organ may be wanting, a fair example being seen in cases of nervous dyspepsia.

One of the earliest manifestations of nervous exhaustion is an irritability or weakness of the mental faculties, as shown by inability to concentrate the thoughts, and efforts to do so causing headache, vertigo, restlessness, fear, a feeling of weariness and depression, together with the army of symptoms attendant on nervousness.

There may be ocular disturbances, cardiac palpitation, coldness of the hands and feet, chilliness followed by flashes of heat, followed in turn by slight sweating. Patients are troubled with insomnia, or fatiguing sleep, accompanied with unpleasant dreams.

In the male there are genito-urinary disorders, with pains in the back, giving the dread of impotence. In females, painful menstruation, ovarian irritation, and irritable uterus.

Diagnosis. It is of importance to determine between a true nervous exhaustion, and nervous debility the result of organic disease. A study of the history of the case, together with the symptoms, should prevent error.

Prognosis. Unless there be a tendency to mental disorders the prognosis is good.

Treatment. Attention to the secretions, diet, and surroundings. *Rest* and diversion of the mind are essential to success. Travel, short of fatigue, pleasant companionship, and relief from responsibility. Bathing, massage, and galvanism are important aids to the management of cases.

Among the internal remedies that are of benefit may be mentioned, arsenicum, strychnina, ferrum, zinci valerianas, phosphorus, extractum cocæ fluidum, vinum cocæ, and syrupus hypophosphitis compositus. Quininæ Sulphas, in small doses, gr. i-ij, daily, for weeks, seems to lessen the excitability of the nervous system.

EXOPHTHALMIC GOITRE.

Synonyms. Graves' disease; Basedow's disease.

Definition. A disease of the nervous system; characterized by protrusion of the eyeballs, enlargement of the thyroid gland, dilatation of the arteries, and palpitation of the heart.

Causes. An undemonstrable condition of the nervous system, either inherited or acquired, is the predisposing cause of Graves' disease. Among the exciting causes are anæmia, shock, fright, chagrin, worry, and reverses of fortune.

It is more common in women than in men.

Pathological Anatomy. "Some structural alterations have been found, in a majority of cases, in the sympathetic ganglia, and especially in the inferior ganglia." (Bartholow.) The veins and arteries of the thyroid gland are dilated, the result of a vasomotor paralysis. The enlargement of the gland is the result of the dilated vessels, and a serous infiltration of its tissues, followed, if long continued, by hypertrophy. A considerable increase of fat behind the eyeballs has been observed. In the majority of cases more or less anæmia exists.

Symptoms. The development of the quaternary of symptoms may occur suddenly, the result of some great shock to the nervous system, but in the majority of instances the symptoms develop slowly and insidiously, with *cardiac palpitation*, with paroxysms of more marked acceleration, tachycardia, the pulse rate varying from 90 to 120, 150, and rarely as high as 200 beats per minute; soon *pulsations*

of the vessels of the neck and thyroid gland may be felt and seen. The enlargement of the thyroid gland—the goitre—appears gradually after the development of the circulatory disturbances, although rarely it may be the first symptom observed. The goitre is elastic, rather soft, and has a thrill similar to an aneurism. The degree of enlargement varies in different cases, and in none ever attains a very great size. Following the development of the goitre occurs the protrusion of the eyeball—the exophthalmos—which may be confined to one eye, but usually occurs in both. Prominence of the eyeball may be the first symptom observed, but usually it does not develop until after the appearance of the goitre. The degree of protrusion varies from a slight staring expression to a point so great that the eyelids cannot cover the balls. Associated with the protrusion of the eyeballs is inco-ordination in the movements of the eyelids and the eyeball, the sign of Graefe, so that when the eyes are quickly cast down the eyelids do not follow them, the sclerotic being visible below the upper lid. Vision is unimpaired. Conjunctivitis may arise, the result of the imperfect protection of the protruding ball by the eyelids.

Associated with the pathognomonic symptoms are nervousness, irritability of temper, headache, insomnia, vertigo, fits of despondency, aphonia, and cough the result of pressure of the goitre, disorders of digestion, increase of temperature, anamia, and loss of flesh.

Diagnosis. The fully developed disease presents no difficulties in diagnosis, but during its incipiency, before the characteristic symptoms have appeared, the disease may be confounded with such conditions as cardiac disease, neurasthenia, lithæmia, malaria, or incipient phthisis.

Prognosis. Recovery occurs in a fair number of cases, but is slow and tedious. The disorders of the circulation lead to dilated heart in many cases, and ultimately death occurs from this cause. Relapses are frequent.

Treatment. One of the first injunctions to be placed on a case of exophthalmic goitre is *rest*, both physical and mental, as well as freedom from worry or emotional excitement; little progress will be made if this point be neglected. The general nervousness, restlessness, and insomnia will often call for special treatment, when use may be made of *chloral*, *potassii bromidum*, *sulphonal*, or *trional*. It is better, however, not to use this class of drugs in a routine manner, but for the special indications only.

The chief indication, next to rest, is the condition of the circulation.

To control this two remedies are of inestimable value; they are digitalis and strophanthus. The results I have seen from tinctura strophanthi, my, from three to six times daily, have been most satisfactory. Dr. Bartholow "has had good effects from quinina, belladonna, and ergotin in combination." I have had a complete and quite rapid recovery, from dried extract of thyroid gland in three-grain doses, twice, and thrice daily. Argenti nitras, gr. ½, after meals, is often a valuable remedy, alternating with strophanthus, or digitalis.

The associated anæmia is to be treated by ferrum, arsenicum, and an easily digestible and nutritious diet. Galvanism to the cervical sympathetic and pneumogastric is an important adjuvant to the medicinal treatment.

TETANY.

Synonyms. Tetanilla; intermittent tetanus.

Definition. A succession of tonic, usually bilateral, painful muscular spasms, occurring at irregular intervals, without loss of consciousness.

Causes. Unknown. Probably a special germ. It has been observed in those having a family history of nervous disorders.

Pathology. The disease is very rare in America, and no lesion has as yet been determined.

Symptoms. Tetany is the occurrence of *intermittent spasms* in the muscles of the arms, hands, legs or feet, or rarely the face and larynx (laryngismus stridulus), associated with *pain*.

The hands are thrown into a position such as they assume in writing, or such as is taken by the hand of a midwife; or the hand may be tightly closed, or one or more fingers may be cramped. The elbows and shoulders may be, at times, affected. In the feet the toes are drawn down and the instep upward, like in equinus. The knees may be cramped or the legs extended.

Any muscles may be involved. Trousseau pointed out that in those suffering from tetany, pressure upon the affected extremities at certain points will excite the spasms.

The *duration* of the spasms varies from a few moments to several hours, the *intervals* being from an hour to a day or more. A certain periodicity is noticed as to the hour of the day or night.

The electro-contractility is increased, as are also the reflexes.

The consciousness is always preserved, although the patients are very nervous.

Diagnosis. Tetanus and tetany may be confounded, and yet trismus is rare in the latter, and always present in the former.

Prognosis. Favorable.

Treatment. Attention to the secretions and excretions, and the use of *potassii bromidum*, gr. xx-xl, well diluted, three times daily.

Gowers recommends digitalis for nocturnal tetany—those painful cramps in the calves in the early morning hours. Urethan, gr. x, every three or four hours, is highly spoken of. Gray says: "Cold to the extremities and ice to the spine have had an excellent effect."

TETANUS.

Synonyms. Lockjaw; trismus; cephalic tetanus.

Definition. An acute or subacute infective disease, characterized by muscular rigidity, with paroxysms of tonic convulsions, the mind remaining clear.

Idiopathic tetanus when no open wound is discoverable.

Traumatic tetanus when an open wound is present.

Tetanus neonatorum when it attacks infants.

Lockjaw or trismus when the jaw alone is involved.

Cephalic tetanus when the throat and face are affected.

Causes. The result of a specific bacillus, which usually gains access to the system through an abrasion.

Pathological Anatomy. In the post-mortem examinations which have been made, no uniform morbid appearance was discovered, on microscopical examination.

The brain, cord, lungs, and muscles are markedly congested, and show minute hemorrhages, such as are met with in all cases of death from convulsions, and which occur chiefly during the process of death.

In four post-mortem examinations of cases dying from tetanus, at the Philadelphia Hospital, marked chronic nephritis was observed. Probably the future may show some connection between nephritis and tetanus, by which the specific poison is not eliminated as it might be were the kidneys normal.

Symptoms. The onset is rather sudden, with *stiffness of the jaw*, *neck*, *and tongue*, and some *difficulty in swallowing*, which increases in extent, the stiffness passing down the spinal muscles to the legs, which are held in a firm *spasm*.

Gradually tonic spasms develop which, involving the jaw muscles,

cause "lockjaw;" the face muscles, "risus sardonicus;" neck and trunk muscles, "opisthotonos;" these tonic convulsions are associated with *intense pain* and the patient suffers the greatest distress, particularly if the chest muscles are involved. Usually the febrile reaction is slight, but in many cases 102° F. to 104° F. is reached and in some instances, as death approaches, 108° F. to 110° F. may occur, rising still higher after death. The mind remains clear till carbonic acid poisoning occurs. Usually a *wound*, not severe, can be found, the symptoms developing some two weeks after its occurrence.

The tonic spasms are developed by any sources of irritation, a draught of air, shaking of the bed or floor, suddenly opening the door of the room, the presence of a visitor, or attempts at speaking or

movement.

Diagnosis. The symptoms are so characteristic, with the addition of a history of a wound, that an error seems hardly probable.

Tetany. The spasms chiefly affect the extremities, the muscles being free in the interval and trismus a late or very rare condition.

Strychnine poisoning often closely resembles tetanus, but there is no beginning trismus and more rapid development of the symptoms. No history.

Hydrophobia does not have trismus, but respiratory spasm, excited by attempts at swallowing, with increasing mental symptoms.

Prognosis. Unfavorable. The great majority die.

Treatment. Rest and quiet in a dark room. Chloral, potassii bromidum, chloralamid, morphinæ sulphas, and paraldehyde are each useful in cases to hold in check or lessen the severity of the spasm for a time. Inhalations of chloroformum will control the spasms, and recoveries have been attributed to its use. Physostigma, and antipyrin, are recommended to remove the spasms.

The nutrition must be maintained; often, on account of the stiffness

of the masseters, rectal alimentation has to be used.

OCCUPATION NEUROSES.

Synonyms. Professional neuroses; artisans' cramp.

Varieties. Writers' cramp; piano-players' cramp; telegraphists' cramp; violin-players' cramp; dancers' cramp.

Definition. A group of affections of the nervous system, characterized by the occurrence of spasm (cramp) and pain in groups of muscles, in consequence of overuse or frequently-repeated muscular acts.

Cause. Undetermined. It has been noticed that many persons suffering from occupation neuroses have a family history of nervous affections.

Symptoms. The symptoms of any of the varieties named generally develop gradually and slowly, by a feeling of *stiffness* in the used member, the part feels fatigued and heavy, until it is impossible to use it, from the occurrence of *spasmodic contractions*; *pain* on using the affected muscles, often associated with *tremor*, and in many cases with an actual *paralysis*.

Associated with the loss of power to follow the usual occupation is *nervousness*, *mental worry*, and often depression. There is often the sensation of prickling and numbness in the crippled member.

The electro-contractility is preserved until the atrophy of non-use develops.

Diagnosis. Calling to mind the history of the case and its results, in being limited to one member, the nature of the condition is evident.

Prognosis. Often unfavorable. Some recoveries are reported.

Treatment. Rest of the part and mental quiet, with tonics and other means to improve the general nutrition. *Faradism* in weak doses once or twice weekly seems useful. The following combination was of value in one case of writers' cramp and in a most aggravated case of ballet-dancers' cramp, each affecting the left limb:—

R.	Zinci phosphidi, .			٠				٠	٠		۰	gr. ij	
	Ext. nucis vomicæ,			۰	۰	٠	۰	۰				gr. x	
	Ferri albuminat,	٠			٠		۰			a		gr. xxx.	Μ.
Ft. p	oil. No. xxx.												
SIG.	One after meals.												

PARALYSIS AGITANS.

Synonyms. Shaking palsy; Parkinson's disease.

Definition. A nervous disease of unknown pathology, characterized by tremors, progressive loss of power in the affected muscles, moderate rigidity, with alterations in the gait and at times mental changes.

Cause. Age seems to be an etiological factor, most cases developing after fifty years. Most frequent in women.

Pathological Anatomy. No characteristic lesion yet deter-

mined. It being a disease of past middle life, there is probably an interstitial hyperplasia of some layer of the cortex, from alterations in the intima of the vessels.

Symptoms. The onset is gradual, the tremor beginning in one of the extremities, oftenest the hand and forearm. At first it can be controlled by the will, for a time at least, and is suspended by voluntary movement. The disease gradually extends until an entire side or the upper or lower limbs are involved. The face and head rarely present tremors but are not exempt. A peculiar rigidity of the affected muscles is characteristic of the advanced stage. "At this stage of the disease the hands are apt to assume the so-called breadcrumbling position, i.e., the thumb and the fingers approximate and move restlessly over one another, as in the act of crumbling bread. There is often a tendency on the patient's part to go forward—socalled propulsion—and this is sometimes so marked that if the patient is once started in a walk forward, his gait becomes more and more rapid, and he cannot stop himself" (Gray). The patients are usually restless and annoyed with insomnia. The general health is fair. The mind is generally retained, although melancholia and mild dementia have been noted in a few cases.

Diagnosis. Disseminated sclerosis has a tremor, but only on voluntary movements—intention tremor. There is also scanning speech and ataxic gait, with mental enfeeblement, as shown by an unnatural contentment with the physical condition and surroundings.

Chorea is a tremor, but the movements are general, and particularly involving the muscles of the face. Again, chorea is a disease of children and young adults.

Prognosis. Radical cure not seen. Improvement often results from early treatment. The disease does not tend to shorten life.

Treatment. The patient should be placed at rest, bodily and mental. Nutritious food, oleum morrhuw, hypophosphiles, and arsenicum.

Hyoscyaminæ sulphas, gr. $\frac{1}{36}$ – $\frac{1}{4}$, three times daily, is a valuable remedy. Good results have followed the use of hyoscinæ hydrobromas, gr. $\frac{1}{106}$ – $\frac{1}{200}$, three times daily. Mild galvanism, twice or three times a week, acts as a nervous stimulant.

MENTAL DISEASES.

MELANCHOLIA.

Synonyms. Depression of spirits; psychalgia.

Definition. A variety of mental alienation, characterized by more or less profound *depression* of the emotions, with either no marked intellectual disturbance, or the presence of more or less incoherence, and the association of hallucinations and delusions. The cerebral mechanism developing a condition of super-sensitiveness, all impressions are exaggerated, and a state of abnormal self-consciousness existing.

Varieties. Melancholia simplex; melancholia hallucinatory; melancholia agitata; melancholia attonita; chronic melancholia.

Causes. Hereditary predisposition. Failing health. Grief. Domestic and financial worries. Neurasthenia. Menstrual irregularities, pregnancy, childbirth, or lactation. Climacteric. Gastric and intestinal irregularities. Alcoholic and sexual excesses. Organic brain diseases. Religion rarely causes insanity, though it frequently gives color to it.

Most common in females and in the young.

Pathology. The alterations in the nerve structure, underlying an attack of melancholia, are undetermined. Anæmia and sluggish nervous energy are constant phenomena, but are hardly the only conditions disturbing the cortex.

Symptoms. Melancholia may be the initial stage of mania, delusional insanity, or paretic dementia, or a stage of *folie circularis*.

Mental: The cardial condition is a feeling of depression, misery, or mental anguish or pain, for which no adequate cause exists. The onset is usually gradual, with a disposition to neglect duties and self, the patients worrying over a something they cannot explain. The world is dark and gloomy, with a foreboding of some awful calamity that is to affect or wreck the patient or his family. Suspicion, distrust, and often, fear of wife, children, relatives, or friends. Insomnia is a constant and stubborn symptom. The memory is maintained, and the reasoning faculties are usually intact, except upon the painful

sensations. The patient may sit quietly or be restless, according to the character of the emotions affected.

Physical: The patient presents either an anxious or a woe-begone expression. Headache, and particularly a post-cervical ache, is a very constant symptom. The skin is dry and harsh, the respirations superficial, the cardiac action slow and feeble; there is gastric catarrh, constipation, and scanty, high-colored urine. The tongue is flabby and coated, and the appetite is poor. The refusal to take food is most characteristic.

Hallucinatory melancholia is an aggravated form of the disease, where, in addition to the painful mental reflexes, are distressing hallucinations and illusions, the patient living in a realm of terror. The attack may be the result of a delusion, but much more frequently the depression and foreboding gives rise to the delusion. The delusions of melancholia are usually of self-accusation, self-abasement and justified persecution; the patient feels that he is being punished for some transgression, imaginary or otherwise.

Melancholia agitata is those sad cases seen in continual agitations, in which the fearful and distressful thoughts and imaginations cause wringing of the hands, and prayers beseeching help, with tears flowing down their cheeks, crying out for assistance and protection. Incoherence and violent impulses are frequent.

Melancholia attonita, or melancholia with stupor, the patients seeming to be overwhelmed, sitting mute, motionless, and expressionless, refusing to assist themselves in any way whatever, often requiring mechanical feeding. Memory is usually impaired in this form; attacks of violence may occur.

Chronic melancholia is the continuation of the depression over a long period, the individual living in the fear of impending danger or punishment for supposed acts for months, often with apparent lucid periods.

Suicidal impulses are present in a fair proportion of cases of melancholiacs, and unless there be everlasting vigilance the patient will succeed in his insane desire.

Diagnosis. The cases of simple melancholia are readily determined. Melancholia agitata is frequently mistaken for acute mania. Melancholia attonita closely resembles acute dementia, a condition, it is but fair to mention, many alienists deny the existence of.

Prognosis. A typical attack of melancholia runs a definite

course, not unlike the typical course of a fever. Favorable in the mild cases of all forms not associated with organic disease, and who have not reached the climacteric. Pronounced cases of melancholia attonita are more apt to terminate in dementia than any other variety.

Treatment. Change of environment, and rest are essential. Attention to the gastro-intestinal canal is of the greatest value, as the dyspepsia and constipation of melancholiac patients is the greatest barrier to their recovery. Frequent bathing, with friction to the surface, aids in the eliminative action of the skin. The diet must be of the most nutritious character the patient can assimilate. If food be persistently refused, mechanical feeding must be practised. The late Dr. Gray was a strong advocate of small doses of opium, or morphina, in acute melancholia, but it has always disappointed me.

Such tonics as quininæ sulphas, arsenicum, ferrum, and strychninæ sulphas are all of value in building up the patient. As the strength improves, open-air exercise must be added to the other means used.

Insomnia must be combated by evening bathing and feeding, and the use of trional, sulphonal, or hyoscina at bedtime.

MANIA.

Synonyms. Insanity; madness.

Definition. An intense mental exaltation, with great excitement, loss of self-control, with, at times, absolute incoherence of speech, and loss of consciousness and memory. (Clouston.)

A mental condition in which there is an emotional exaltation, accompanied by illusions, hallucinations, delusions, great mental and physical excitement, and a complete loss of the inhibitory power of the will; in acute cases, and frequently in chronic forms of the disease, there is a marked destructiveness and a tendency to violence. (Wood.)

An attack of mania may be acute, subacute, or chronic.

Causes. Inflammation or other organic disease of the brain or its membranes. Mental shock or strain. Worry—domestic, moral, or financial. Excesses in alcohol, venery, or tobacco. Ovarian disease, or menstrual irregularities. Climacteric in those of nervous disposition. Pregnancy, parturition, or lactation. Nephritis. Anæmia. Syphilis. Hereditary predisposition.

Pathology. There are no constant morbid changes associated

with mania. In all varieties of acute insanity there exists vitiated nervous energy or impaired vitality, the result of over-excitement or over-stimulation, motor disturbance, or auto-infection, the result of the imperfect elimination of the products of tissue waste. "There is no reason why a mere dynamical brain disturbance should not kill and leave no structural trace, any more than that it should for months abolish judgment, affection, and memory, and then pass off and leave the brain and all its functions intact." (Clouston.)

If death follow acute symptoms, the vessels of the brain and membranes are engorged, but in the majority of instances the brain structure is normal.

If death occur in chronic mania, the most frequent change found will be a thickened and adherent dura mater. As observed, any form of organic change may be found *post-morten* in those dying of any form of mania.

Symptoms. *Acute mania*: The onset may be abrupt, or following a period of emotional depression, associated with lassitude, feeling of unrest, disinclination to work, and disorders of the gastrointestinal canal, with insomnia and an *introspection*; these symptoms are termed the melancholiac stage of mania.

The maniacal stage is characterized by loud talking, intense egotism, violent motions of the limbs and body, great restlessness, and excitement; the thoughts flow in wonderful freedom and with amazing rapidity, the condition often resembling the symptoms of early alcoholic intoxication; as the condition continues the patient becomes either sullen, irritable, and angry, offering violence to those around him, or he becomes garrulous, talking of his personal affairs, is confidential and communicative to strangers, often making egotistic offers, passing frequently into incoherence of language and action. Sexual passions are frequently exalted, and acts of masturbation practised. Delusions are an almost constant symptom, of a superficial or transitory character, changing with every new appearing mood. The maniacal patient is sleepless, or may have short naps, at once continuing his chatter on awakening.

Any attack may show all of the symptoms mentioned, or any one or more of them, but the great majority of cases show intense egotism, loud talking, violent motion of limbs or body, hurry, excitement, insomnia, incoherence, and incessant noise.

The course of an attack is periods of remissions and exacerbations,

with nocturnal crises; loss of flesh and mental weakness are often marked as the attack progresses.

Acute delirious mania, typhomania, is a psychosis of sudden onset, attended with increased bodily temperature, and marked by delirium with sensuous hallucinations, marked incoherence, restlessness, refusal of food, loss of memory, and rapid bodily wasting, terminating frequently in death.

Mania amenorrhwal is often used for attacks of mania occurring at the menstrual epoch. Homicidal, suicidal, and various hysterical impulses are frequent.

Mania-a-potu is an attack of acute delirium, due to alcoholic excesses in those engaged in a sudden debauch, or who have drunk heavily and eaten little, for a comparatively short period.

Mania asthenic, in which there is general anæmia associated with neurasthenic symptoms.

Mania chronic; a condition of continual mental exaltation, the acute symptoms having continued in a chronic course. The line that distinguishes between an acute and a chronic mania must always be somewhat arbitrary and unscientific. The duration of the mania beyond twelve months, is usually considered sufficient to determine the condition, and this is well, as it precludes the possibility of terming the condition incurable. If the term chronic mania was restricted to those cases in which, between the exacerbations of restlessness, excitement and destructiveness, were evidences of dementia, less confusion would occur.

Mania dancing is a hysterical mental state in which, through sympathy and imitation, dancing of a most grotesque and extravagant character occurs. Usually epidemic.

Mania delusional is the result of fixed delusions, either causing or associated with the maniacal outbreak.

Mania erotic, erotomania, presents systematized delusions of an erotic character, not necessarily accompanied by animal sexual desire. Nymphomania is a morbid, irresistible impulse to satisfy the sexual appetite, peculiar to the female sex.

Mania epileptica follows an epileptic paroxysm, and is often of a most violent kind, the maniacal acts being of the most treacherous and malicious character.

Mania hallucinatoria presents visual, auditory, olfactory, and other sense hallucinations.

Mania homicidal is any variety of mental disease in which there is a desire or an attempt on the part of the patient to commit murder. The condition may be the result of delusions that the persons attacked either are persecuting, or going to kill the patient, or of the excessive excitement that vents itself in destructiveness, combativeness, or desire to kill, or there may be a morbid desire, impulse, or craving to do murder, or the homicidal act may be unconsciously done during an acute delirium, or a paretic, or epileptic maniacal impulse.

Morphiomania is the insane craving for the stimulating action of morphia—a moral insanity.

Mania puerperal is the maniacal outbreak as seen in the puerperal woman. This is now thought to be of septic origin, although the mental strain through which the female has been passing is a pre-disposing factor.

Mania recurrent, or chronic mania with lucid intervals of longer or shorter duration. Generally of alcoholic origin.

Mania transitoria, or ephemeral mania, is a rare form of maniacal excitement of sudden onset, violent and decided in character, accompanied by great insomnia, incoherence, and more or less complete unconsciousness of familiar surroundings. The attack as suddenly terminates, the duration being from a few hours to a few days.

Mania senile is the mental exaltation occurring in persons with senile arterial changes, or senile cerebral atrophy. Soon followed by dementia.

A maniacal outbreak may present any one, or a number of the varieties named.

Terminations of Mania. About fifty per centum of acute manias, not due to organic disease, recover after periods varying from one month to several years. A fair proportion of cases make a partial recovery, and are able to return to their work, but always showing some alteration in character or affection, or some eccentricity, or a slight mental weakness. About twenty per centum of cases terminate in dementia or mental death, and this is always the fear in each case. Two per centum of cases die, either the result of exhaustion or from the organic condition causing or associated with the attack.

Prognosis. The question of recovery, partial or complete, is always difficult to determine, depending upon the cause, temperament, disposition, education, nationality, and the normal mentality of the individual. Recovery is usually gradual; rarely sudden restoration occurs.

Favorable indications are: sudden onset, short duration, youth of patient, absence of fixed delusions, good appetite, increasing hours of sleep, moderate or no increase in temperature, pulse, and respiration, no evidences of mental weakness, no paralysis or alteration of pupils or articulation, no epilepsy, no unconsciousness to the calls of nature, and no former attacks. Unfavorable indications are the opposite of these, and also the presence of organic brain disease, or a strong hereditary inheritance, or the possession of an excitable disposition, or nervous diathesis.

Treatment. The indications for treatment are to quiet the exalted mentality and to promote constructive metamorphosis. Every means should be used to lessen the excitement of the patient and produce refreshing sleep. A hot or warm bath is frequently one of the most soothing means of reducing excitement; changing the environment of the patient and placing him under the care of a good, firm, but kind and intelligent attendant is of importance. If means of this character are unavailing, and, unfortunately, in the majority of attacks they will be, then resort must be had to sedatives, for every day's continuance of the maniacal outbreak lessens the chances of restoration. Amongst the drugs having a distinct value are hyoscinæ hydrobromas, gr. $\frac{1}{200}$ - $\frac{1}{600}$, repeated once or twice daily, watching its effect on the pupils; sulphonal, gr. xx, repeated with caution, watching its effect upon the heart and respiration; chloralamid, gr. xxx-xl, repeated three or four times daily; or, trional, gr. xxx, repeated in two or four hours; this latter is one of the most reliable drugs for maniacal excitement and insomnia we now possess. Patients with much excitement and a weak pulse are benefited with full doses of the bromides and digitalis. If the muscular excitement is pronounced, good results follow morphinæ sulphas, hypodermically; it may be combined with, either atropinæ sulphas, hyoscinæ hydrobromas, or duboisinæ sulphas. In attacks of acute mania, with flushed face, throbbing arteries, full pulse, and delirious excitement, excellent results follow the use of extracti gelsemii fluidi, mij, every hour, until dilatation of the pupils and ptsosis occur, unless improvement sooner occur; tincturæ veratri viridis, mij-v, is also useful. Post-epileptic excitement is best controlled with large doses of chloral, by the mouth or rectum. Ice, or cold to the head, is useful in cases with flushed face and throbbing temporals.

The general condition of the patient needs the most prompt and

efficient treatment. Attention to the gastro-intestinal canal and kidneys is of paramount importance, as many attacks of mania are the result of auto-intoxication from the retention of the products of malassimilation and tissue waste. The diet should be of the most nutritious character, administered at frequent intervals—peptonized or hot milk, hot broths, eggs, and often alcoholic or malt liquors.

Patients not infrequently refuse food on account of lack of appetite, abhorrence for food, or from fear of poisoning, when recourse must be had to the naso-stomachic tube, or nutritive enemata.

Tonics are of great value, a combination like the following always being beneficial:—

R.	Quininæ sulphat.,							gr. xlviij	
	Strychninæ sulphat.,							gr. ss	
	Acid. hydrochlor., dil., .					٠	٠	f z iij	
	Aquæ chloroformi,								
	Aquæ menthæ pip.,			ad	q.	S.	٠	f 🕱 vj.	M.
Sic.	-Descertspoonful diluter								

The question of removal to a hospital for the insane arises in nearly all cases, and should in my judgment be answered, in the vast majority of instances, in the affirmative, as the discipline, regular hours, and order of a well-managed hospital for the insane, has a most remarkable effect on the majority of insane patients.

EPILEPTIC INSANITY.

Definition. A mental condition caused by or the result of epilepsy.

Causes. The careful study of the brain of those dying having epileptic insanity has failed to determine why some epileptics suffer from any of the insanities and others have their normal mentality, and another group are better after a convulsion.

I am familiar with ten cases of epilepsy who all seem much brighter, mentally, after their paroxysm, but in whom, after a drinking bout, each epileptic attack is followed by a wicked homicidal mania of many months' duration.

Varieties. Pre-epileptic mania; post-epileptic mania; dementia epileptica; imbecility with epilepsy.

Symptoms. The mental changes constituting epileptic insanity, save in the cases of epilepsy with imbecility or idiocy, develop after some years of the ordinary epileptic paroxysms.

Pre-epileptic mania has attacks of mania some days or hours preceding the epileptic convulsion. The patient is morose, irritable, and threatening, often making homicidal attacks on those around him, be they friend or foe. Rarely the epileptic seizure is replaced by various insane, or so-called hysterical acts, as fits of dancing, laughing, crying, screaming, swearing, or scolding.

Post-epileptic mania follows the epileptic paroxysm, either taking the place of the comatose stage or following after it. The maniacal acts during these outbreaks are often of the most desperate and impulsive character, many an asylum physician and attendant carrying scars, the result of attacks of post-epileptic maniacs.

Epileptic dementia is the terminal mental obliquity resulting in about thirty per centum of insane epileptics, who do not succumb before to nephritis or tuberculosis.

Epileptic imbecility is a congenital condition in which the two conditions are associated.

Prognosis. The great majority of cases of epileptic insanity develop, sooner or later, either nephritis or tuberculosis.

Recoveries from epileptic mania is a rare occurrence, although I am familiar with two cases. Thirty per centum of epileptic maniacs progress to dementia in from five to ten years.

Treatment. There is no doubt but that full doses of the bromides lessen the severity and frequency of the paroxysms. If the attack can be anticipated, it may sometimes be averted by an enema of chloral, gr. xx-xxx, or chloralamid, gr. xl-lx; or amyl nitris, m.y. by inhalation, or by stomach.

The general condition of the patient must receive careful attention, as there is a strong tendency to the development of nephritis, tuber-culosis, and gastric catarrh. This class of patients are great feeders often gluttons—and are sure to eat more than they can properly assimilate.

Never contradict, nor attempt to reason with, an epileptic, during their period of excitement.

CIRCULAR INSANITY.

Synonym. Folie circulaire.

Definition. A mental disease characterized by regularly alternating and recurring periods of mental exaltation, depression, and sanity,

Causes. Hereditary predisposition. The exciting causes are any of those conditions which depress the brain or general system.

Pathology. There is no characteristic lesion associated with circular insanity.

Symptoms. Essentially a chronic condition and probably incurable. The disease usually begins as a *melancholia*, the depression being an apathy and torpor rather than a mental pain; and suicidal feelings and impulses are rare; this condition is soon succeeded by a *mania*, a mental exaltation with hyperæsthesia and exaggeration of nervous functions, the reasoning power well retained; this is in turn followed by a *lucid interval*, often giving promise of recovery, to be sooner or later followed by another cycle. These periods follow each other with remarkable regularity, each being of the same duration. Rarely the various periods are of irregular duration.

The general health is well maintained, the patient gaining in flesh during the stages of depression and lucidity and losing during the period of exaltation.

Diagnosis. The regularity of the different periods soon establishes the diagnosis.

Prognosis. Generally incurable.

Treatment. Attention to the general health and meeting the symptoms of the different periods as they recur.

KATATONIA.

Synonyms. Alternating insanity; Kahlbaum's insanity.

Definition. A mental disease, characterized by irregular cyclical symptoms, ranging from melancholia to mania, followed by stupidity and confusion, with cataleptoid phenomena, followed by lucidity for a time, recovery, or passing to a dementia.

Causes. Hereditary predisposition. The exciting causes are usually the result of some excess. Rarely associated with organic brain disease.

Pathology. No characteristic lesions have been found associated with katatonia.

Symptoms. A typical case begins as a *melancholia*, the mental depression, uneasiness, and distress followed after a variable period by *mania*, associated with hallucinations and delusions. This period is followed in turn by a condition of *attonita*, or rigidity and immobility,

or a cateleptoid paroxysm: any of the stages may be followed by confusional symptoms, or a true dementia may develop. During the maniacal stage there is a tendency, in many cases, to histrionic and sermon-like declamation, or the speech may be of the verbigeration character—that noisy, incoherent, and meaningless speech seen in many manias, composed largely of the constant repetition of a few words or phrases.

During the stage of attonita the presence of the so-called *mutism* or *mutacismus*, "a pathological tendency to be silent," may continue for days, weeks, or months, or it may be interrupted by periods of verbigeration.

The immobility or rigidity so characteristic of a period of katatonia is frequently alternated with automatic, incessant, and monotonous movements—the stereotyped movements.

Patients suffering from katatonia often refuse food for days at a time and then suddenly present symptoms of boulimia. Vasomotor and trophic changes are frequent, one of the most constant being *cyanosis* of the hands and other peripheral parts. Hæmatoma auris, insane ear, or perichondritis auriculæ, is frequent. Epileptiform attacks may usher in the disease or occur during any of its stages.

Diagnosis. It may be diagnosed as melancholia, mania, or a dementia, depending upon which of the cycles be first observed, but after being under observation long enough to observe a complete cycle, the diagnosis is readily determined. Katatonia differs from circular insanity in the absence of a genuine lucid interval, and the presence of the stage of attonita and catalepsy.

Prognosis. The disease may continue for a number of years and recovery follow, but as a rule the prognosis is unfavorable.

Treatment. Attention to the general condition, and combatting the various symptoms as they arise. In cases associated with anæmia, arsenicum, and strychnina, seem to be valuable. Two cases were rapidly improved with small doses of hyoscinæ hydrobromas, gr. $\frac{1}{200-300}$ morning and evening.

DELUSIONAL INSANITY.

Synonyms. Delusional mania; delusional melancholia; primary delusional insanity.

Definition. A mental state, with fixed or partly systematized

delusions, associated with either brain exaltation or excitement without maniacal acts, or a mental depression, minus the somatic symptoms of melancholia.

"An insane delusion is a belief in something that would be incredible to sane people of the same class, education, or race as the person who expresses it, this resulting from diseased working of the brain convolutions."

Causes. Cerebral and bodily exhaustion the result of overwork, neglect of personal hygiene, or alcoholic, tobacco, drug, or sexual excesses—a neurasthenia. Impairment of the nervous centres, the result of fevers or shock. Climacteric period, worry, and insufficient food.

Pathology. Delusional insanity is a subacute, or chronic condition; death seldom occurring, and when it does ist he result of an intercurrent physical malady. In the few such cases in which postmortem examinations have been made, the vessels of the brain were found torpid or dilated—a vasomotor paresis causing an imperfect cerebral circulation.

Symptoms. Either following an attack of acute mania or melancholia, but more commonly without either of these conditions, occurs a set delusion or delusions, which, to the patient, are so real that no amount of argument can dispel his or her belief. These cases are often classed as manias or melancholias, but, as they do not run the ordinary course of either of these conditions, they are best classed clinically by themselves. The acuteness or subacuteness of the attack distinguishes them from paranoia. Amongst the almost endless variety of delusions I will mention a few that have come to my notice recently: A young man of twenty believes he is President Cleveland; another patient, a driver, believed for ten months he was the owner of a thousand horses, any one of which was worth thousands of dollars; he made a perfect recovery and now laughs at his old delusions. A young man of twenty-five believes his mother is not his mother, but the woman he boarded with, and that his brothers and sisters are her children and no relation to him. A young woman of thirty believes she is pregnant by a prominent merchant; the fact being she is not and never has been pregnant. The majority of the delusions are of an egotistical character, but lack the conduct or appearance of the position due to the character of the delusion. A patient with ragged clothing will assure you that he is worth millions, and yet sees nothing inconsistent between his delusion and his personal appearance.

Another will assure you of his vast business interests, and yet remains contented in the hospital wards, laboring faithfully in the kitchen or laundry. A woman assures you she is the great Patti, receiving thousands of dollars for each operatic performance, and yet is apparently happy in the sewing-room.

Delusional insanity is often based upon the development of hallucinations of the special senses, that of hearing being the most frequent; patients hear "voices" telling them what to do or not to do, and a delusion is built up and developed; again, "voices" upbraid them, or charge them with various acts, and upon this is developed a persecutory delusion that causes them much unrest. The following case has lasted for five years, and while the patient is at times apprehensive of some evil that may result to her, and uses judgment to protect herself, yet is not, nor never has been, melancholiac, or shown any evidences, other than her present belief, of mental failure. She enjoys fair health and partakes of the world's pleasures. Six years ago her husband suddenly died and the settling of a large estate was thrown upon the patient. Sitting in her hotel, at the window, about five years ago, she saw a man come to the window, in a building opposite to where she was, and make some motion to her. She was greatly alarmed. That evening, while walking on one of the busiest streets of the city, she distinctly heard a young man, in passing, make an improper proposal to her, and she has never walked on that street since without the same thing occurring, although not always by the same person. Her daughter, who accompanied her, did not hear the proposal, nor has ever heard it, although, I regret to say, is gradually becoming convinced it must be true. Now for the sequel: the woman is not depressed or worried, shows no evidences of melancholia, talks about the affair as if it were a fact, which it unfortunately appears to her, and avoids the unpleasantness by never again walking on the particular street nor going in that neighborhood.

Again, visions appear which result in delusions of personal importance. Taste and smell may be perverted, causing prolonged fasting, often from fear of poisoning.

Diagnosis. Delusional mania and delusional melancholia are confounded with delusional insanity, the points of distinction being the absence of severe maniacal and melancholiac acts; the patient simply possesses his insane delusion and may never refer to it unless questioned. Paranoia or monomania and delusional insanity have

many symptoms in common, but in the former, if the patient believes he is Christ, he wishes to be so respected, and considers himself wronged if not so treated, while the delusional patient will say he is Christ and immediately drop the subject. There are, however, many border-land cases in which the diagnosis is difficult.

Prognosis. Recovery the rule, although the delusions may exist for a number of years. Many patients who make a complete recovery will still believe that their delusions were facts.

Treatment. A supporting plan of treatment, with thorough action upon the bowels, kidneys, and skin, and plenty of fresh air, is of great value in all cases of delusional insanity. If the disease is the result of excesses, a course of *stryclinina*, and *arsenicum*, are indicated. A tranquil condition of the brain is essential, and few combinations are so valuable as *digitalis*, and *hyoscina*, in small, repeated doses. Insomnia is an annoying symptom in many cases and is best overcome by a digestible meal at bed-time, or a warm or hot bath in the evening, and if these fail a full dose of *somnal* well diluted, or *trional*, gr. xxx, an hour before bedtime, in milk or spirits.

PARANOIA.

Synonyms. Monomania; chronic delusional insanity; reasoning mania; verrücktheit.

Definition. A chronic mental disease characterized by fixed logical or systematized delusions of persecution, unseen or impossible agencies, or of self-exaltation, the emotions and memory being only paroxysmally defective, while, however, the life of the individual is dominated by the delusions.

The term paranoia, as it is now commonly used, to cover a group of insanities which are degenerative in origin, chronic in course, and characterized by systematized delusions, with little impairment of the emotional faculties, is not generally accepted as a synonym for monomania.

Causes. There is generally a hereditary predisposition to insanity in monomania or paranoia. The exciting cause may be the result of an acute mania or melancholia, or the result of alcoholism, or the result of malnutrition in those who have had a struggle to keep their position in the world. Extreme worry in individuals with mental instability. Following primary or acute delusional insanity.

Symptoms. The course of monomania is essentially chronic, the delusions becoming perfectly fixed and unchanging upon one particular subject or sets of subjects, which in turn dominate the life of the individual. The most common character of these systematized delusions are, delusions of persecution or suspicion, delusions of exaltation or of pride, and delusions of unseen agents or influences.

A delusion of persecution is shown in a woman of average talents and education, who has devoted much time, thought, and worry to a number of worthless patents, and now that she is in an insane asylum believes she has been placed there that others may reap the rewards of her inventive genius; she is constantly annoyed by what the physicians, attendants, and patients are doing, claiming that many such acts are for the purpose of annoying or harming her, her suspicions being of the most aggravating character.

Delusion of exaltation or pride is well shown in the case of a man who believes he is Jesus Christ, and is angered to the point of almost homicide if great consideration is not shown him. Another male, whose origin is from the lower walks, believes he is to marry a distinguished authoress, and will resent any doubt of his purpose with blows.

Delusion of unseen agencies is well shown in case of a female, aged forty years, who labored under the delusion that she was beset by numerous devils in her abdomen, the real cause being the presence of a cancer of the liver. Patients complain of electrical influences, telephonic communications, and invisible agents tormenting them.

The range the delusions of monomania assume are most wide and varied, but always associated with the ego. The patient is being persecuted not because, as in melancholia, he has committed some sin, or thinks he has, and deserves punishment, but because the persecutors wish to deprive him of his rights, titles, or estate, or degrade him or in some way injure him.

Diagnosis. In the diagnosis of monomania there are three points to ever keep in mind; first, the duration; the fixed, systematized delusions must have existed over one year; second, the absence of symptoms of mania or melancholia; and third, the presence of systematized delusions affecting the personnel of the individual.

Prognosis. Monomania is an incurable disease. Unless tuberculosis develop within a few years, dementia results.

Treatment. Symptomatic, and all means that promote constructive metamorphosis.

DEMENTIA.

Synonym. Acquired feeble-mindedness.

Definition. A progressive general weakening of the mind, characterized by a loss of reasoning capacity, a diminution of feeling, a weakened volitional and inhibitory power, failure of memory, associated with lack of the power of attention, interest, and curiosity, in varying degrees, in an individual who at one time possessed these mental qualities.

Forms. Dementia acute; dementia alcoholic; dementia apoplectica; dementia choreica; dementia chronic, or secondary; dementia epileptica; dementia organic; dementia paralytica; dementia partial; dementia primary; dementia secondary, sequential, or chronic; dementia senilis; dementia syphilitica; dementia toxica.

Causes. Deficient or feeble mental inheritance; age; atheroma; following mania, melancholia, paranoia, and other forms of insanity; the result of organic brain conditions; alcoholism; syphilis; developmental changes; climacteric.

Pathology. In acute dementia the changes are dynamic. In the primary dementia there is probably atrophy of certain cells from over-stimulation, the tissues being normally deficient. In secondary dementia the chief changes are, "alteration in the size of the vessels, owing to thickening and distention, the thickening being most marked in the deep layers, and in the walls of the vessels are fatty granules and hæmatoidin. The perivascular canals are enlarged. The changes in the cells may be described as deficiency in the number of pyramidal cells, and a want of distinctness of outline and branches, the nuclei being larger, but changed in form, and only capable of slight carmine staining." In senile dementia there is general atrophy and degeneration of all the tissues of the brain.

Symptoms. The onset, extent, and variety of the impaired mentality differs greatly. In some patients the evidences of the failing mind are seen with the subsidence of the mania, melancholia, or other insanity, or soon after the development of the particular cause, while in another group of cases the development is slow and insidious. The difference in the intensity is marked; in one case the changes being scarcely noticeable, the patient being simply less active than before, showing a slight indifference to his environment, while in others, the patients remain for hours alone, making no effort at movement and with little or no expression of the face,

while another class of cases are oblivious to the demands for food or drink, or the calls of nature, existing "in the darkness of perpetual intellectual and moral night." Between these symptoms are all varieties and degrees of mental enfeeblement, the *physical symptoms* of dementia varying with the particular cases, many enjoying the best of health, eating and sleeping well, while others are always unwell, first one organ and then another, while another group suffer from chronic diarrhea, which finally causes death. Dementia patients seem predisposed to tuberculosis, nephritis, and apoplexy.

Acute dementia, or "stupor with dementia," is to be distinguished from "stupor with melancholia." The onset is rather sudden, with or without mania or melancholia, after some brain or bodily exhaustion, shock, or fright; the patient, a young person, "is horror-stricken. paralyzed in mind, not merely deranged, not depressed or excited, but deprived of feeling and intellect; his movements, if there be any, are automatic, but frequently he is motionless, standing or sitting, staring at vacancy for hours and days" (Blandford). These patients will not converse, and do not reply to questions, or but slowly, and in monosyllables, and their face has a blank expression. One young man of twenty-three years, but three years in America, having an extraordinary musical education, and a remarkable skill as a piano performer, being unable to secure pupils to teach, was obliged to accept a position as a piano-player at a questionable summer-resort garden, where he contracted the alcoholic and sexual habit. His excesses increased, although never intoxicated; he suddenly developed symptoms of dementia, his mind becoming a complete blank, his circulation feeble, the surface cold; and he never offered to enter the dining-room, and yet attended to the calls of nature. He never spoke, and would remain alone and motionless for hours. The sweetest music caused no movement showing intelligence. He was placed on the Mitchell rest treatment for six weeks, and, as his bodily condition improved, he was daily taken to the piano, and his fingers made to touch the keys. For weeks he showed no interest, when, slowly, one day he feebly ran his fingers over the keys, and from that day improved, until, within four weeks, his performance on the piano attracted wide attention, and, after recovery, which was complete, with no recollection of this sickness, he secured pupils and is to-day a successful teacher. He has assured me that he suffered no pain, no depression, but that all is a blank to him.

Dementia alcoholic, the mental weakness resulting from excessive

use of alcohol. *Inebriety* is a form of dementia, there existing an uncontrollable alcoholic habit with weakened or absent will power, and impaired mentality.

Dementia apoplectica, an organic or terminal dementia due to the cerebral changes sometimes following a severe apoplectic seizure.

Dementia choreica is a feeble-mindedness associated with chronic chorea or, in some cases, probably the result of the chorea.

Dementia chronic is the designation applied to all forms of dementia that have existed after one or more years.

Dementia epileptica is the slow mental impairment resulting from long-continued and frequently occurring epileptic convulsions.

Dementia organic, the mental deterioration resulting from gross organic brain lesions, such as sclerosis, tumor, embolism, or trauma. An intelligent machinist, aged forty years, fell a distance of twenty feet, striking on his head, but not causing any determined fracture. He was unconscious one week, and on slowly recovering it was noticed that there was some change of character, which has grown most decided, and is associated with persistent insomnia. He is restless, indifferent, has loss of memory, is vulgar and profane and inclined to be talkative, opposite traits to his former self, has violent outbreaks, and has a delusion that he is to make a fortune out of a polish, the formula for which was given him by God, but which he has mislaid. He cannot read or write, or, at least, he will never make the attempt. His physical condition is good.

Dementia paralytica is a synonym for general paralysis of the insane.

Dementia partial is an incomplete form of dementia, in which the mental enfeeblement is associated with such a degree of intelligence and memory that the qualifying term "partial" is correct.

Dementia primary is seen most frequently in the young, developing slowly and insidiously, without any symptoms of mania or melancholia, usually in a youth who has given promise of a bright future, by a slowly progressive indifference to his former occupation, studies, or surroundings, with developing carelessness and negligence of person and proprieties, no amount of external stimulus serving to rouse the receding mentality, until finally the downward course ends in dementia so decided that, but for the history of the individual, the case would be classed as a congenital.

Dementia secondary, sequential, or chronic, is the most common variety of mental impairment, following mania, melancholia, and other

insanities. According to Bevan Lewis, twenty per centum of manias, and fifteen per centum of melancholias, become permanent dements.

Dementia senilis, the result of cerebral atrophy, with its consequent failing mental power. Loss of memory for recent events is one of the most common symptoms. The disease often begins as a senile mania, melancholia, or delusional insanity. A female aged sixty years, with intemperate history, was, on admission, exceedingly filthy and with many vermin. She says she has been persecuted in her poverty; that she could not obtain goods from the store when she had no money, though the shopkeeper was rich; that she was neglected by others; insists that she ought to have been assisted, is unconcerned with her surroundings, is trifling and disrespectful, restless, moving her hands and body almost continually, is childish and silly in manner, frequently laughing, claiming she is happy and will not work, cannot remember her only sister's name or where she herself last resided.

Dementia syphilitica is the feeble-mindedness resulting from cerebral syphilis. This group of patients are always sanguine and assert they are "all right," "never sick in my life," and yet unable to assist or care for themselves.

Dementia toxica is the mental failure produced by the long-continued and excessive use of opium, cocaine, and chloral. Chronic plumbism is also given as a cause.

Diagnosis. Acute dementia is often misnamed, melancholia with stupor, but if the patient is in the teens the probabilities are that it is a case of the former, while if past forty it is almost certainly the latter.

The distinction between dementia and idiocy or imbecility must always be determined. Esquirol's graphic description is well worth remembering: "The dement was a rich man who has become poor; the idiot, on the contrary, has always been in a state of want and misery."

Prognosis, Acute dementia is generally favorable. All other varieties are incurable. The average lifetime of dements is placed at about twelve years, the great majority dying of tuberculosis, nephritis, or apoplexy.

Treatment. Patients suffering from acute dementia should be placed on the Mitchell rest regimé, with attention to all the secretions. If Dr. Mitchell's directions are carefully followed, the great majority of cases of acute dementia will recover within nine to twelve months.

For the other forms of dementia, unfortunately, there is no cure, the treatment resolving itself into attention to the general health, with proper custodial oversight.

GENERAL PARALYSIS.

Synonyms. Paralytic dementia; general paresis; general paralysis of the insane; dementia paralytica; paresis; paretic dementia

Definition. A subacute, or chronic, degenerative, disease of the brain, sometimes involving the spinal cord; characterized by *alterations* in the intellectual and moral character, with the development of unsystematized ideas of self-importance, or delusions of grandeur, finally merging into dementia (preceded by either a mania or a melancholia), and the gradual development of tremor, slurring speech, pupillary changes, ataxia, tropic changes, and finally paresis.

Causes. General paralysis occurs chiefly between thirty and fifty-five years of age, and in the male more frequently than in the female. It usually affects the robust, middle-aged individual, rapidly destroying all intelligence and judgment, leaving him to exist, often for months, as a demented human automaton.

Predisposing causes; hereditary; an ambitious over-straining for prominence, learning, or wealth; forced intellectual activity in those with imperfect or improper early training; cranial injuries; atheroma.

Exciting causes; alcoholic and sexual excesses; syphilis; mental and physical overstrain; worry. "In many cases I think the middle-aged general paralytic is suffering for the sins of his youth" (Clouston). "General paralysis is not a penalty of high cerebral development, but the expression of a discrepancy—an inadequacy of some brains to sustain the strain to which the race, as a whole, is subjected" (Spitzka).

Pathological Anatomy. A condensed description of the pathological basis of general paralysis is difficult. It may be described as a chronic diffuse cortical encephalitis. The microscopical changes in the cortex, according to Mendel as quoted by Folsom, are as follows:—

I. Increase of nuclei and new cell formation, some nuclei small, some large, and with such varying reactions to coloring agents as to suggest dissimilarity of origin. The stellate or "spider" cells are increased in the upper layer of the cortex, where some may be normally found, and extend to lower layers, as is not the case in normal brains; they, too, may be several times the usual size and also push through the white substance to the ependyma of the ventricles. Pro-

liferation of neuroglia or connective tissue, and in time sclerosis of the cortex, which involves the medullary substance also in a greater or less degree.

2. The larger blood-vessels may or may not be atheromatous; in the capillaries there is an increase of nuclei in the walls, with thickening and hyaloid degeneration.

3. In the nerve cells, the ganglion cells, granular and fatty degen-

eration of protoplasm, sclerosis, atrophy.

4. Atrophy and final disappearance of the nerve-fibres, not limited to the cortex and found in other brain diseases also—senile dementia and epilepsy, for instance.

5. Focal lesions of the most various kinds, and degenerative changes in the spinal cord, the several forms of sclerosis and mye-

litis.

The spinal cord undergoes atrophy with grey degeneration in posterior and posterior-medium columns, and of posterior spinal nerveroots.

Symptoms.—For clinical convenience the disease is divided into three stages, prodromal, maniacal, rarely melancholiac, and the stage of dementia, although there is seldom a marked division between each.

Prodromal stage may exist unrecognized for months or longer. It begins by an alteration in the habits and character of the individual; the patient has spells of irritability and obstinacy, which will not admit of contradiction or opposition; there is a general feeling of elation and bien-etre, an egoism shown by the exalted opinion of his own attainments and importance, and a great laudation of his family. He becomes boastful, untruthful, dishonest, and forgetful, neglecting engagements, business, self, and family. He frequently makes extravagant purchases and may waste large sums of money before his condition of irresponsibility is recognized, or, may unwittingly resort to dishonest means to obtain money to squander on newmade friends, as was shown in the case of an intelligent gentleman, who had squandered considerable money in unprofitable property, going to a railroad ticket office, asking for a ticket, remarking he was without cash, writing a check for one hundred dollars on a bank he never had an account with, receiving ninety-nine dollars in change, immediately going to a jewelry store and purchasing a lady's gold watch and chain, paying sixty dollars for the same, and then going

to a pawnbroker's and pledging the watch and chain for forty dollars, and the following day going to the same ticket office and buying another ticket of the same kind he had purchased with the fraudulent check, and on being arrested protested he had done nothing dishonest. In many instances the patient develops ideas of an enterprising character, and resorts to all forms of expedients, which, to his mind, are going to improve his or his family's station and worldly condition; he determines to change his occupation or business, or attempts to instruct the authorities in what he conceives should be their duties. The moral lapses of paretics are most frequent during this stage, consisting of acts of theft, drunkenness, violent impulses or indecent assaults, in individuals who have possessed a good moral character. They become profane and vulgar, and often resort to sexual excesses. Associated with any of the above symptoms may be any one or more of the following physical conditions: tremor of the muscles about the mouth, naso-labial folds, and of the tongue, causing a slight slur or hesitating speech; alterations in the pupils, or one pupil becoming somewhat larger than the other; attacks of vertigo, or epileptiform or apoplectiform seizures; the gastric, intestinal, hepatic, and nephritic secretions are disturbed, and there may be headache and insomnia. After a variable duration, continuing in a mild degree for many months, is ushered in the-

Second, or maniacal stage, which is much the same as a severe attack of acute mania, plus the physical signs of paresis and the delusions or ideas of grandeur. The patient is excessively restless, boasting of his great wealth, intentions, prospects, and influence, one moment the most important of individuals, the next giving away thousands, and if doubt is expressed as to his ability to do so, making it millions and often billions, presenting houses and lands, titles and offices, with unstinted liberality. It is to be noted that these so-called delusions of the paretic are in reality conceptions, or an expansive delirium, for when contradicted the patient makes no effort to defend them; they seem to be really assertions and reassertions, continuing until incoherency restrains the airy imagination. The patient is sleepless, noisy, destructive, with attacks of blind, uncalculating violence, resisting all who attempt to restrain or molest him; the violent impulses of paretics are similar to the furious excitement of the postepileptic maniac. The physical signs are more pronounced, the characteristic hesitating and slurring speech increases, the pupillary changes become more marked, the tremor of the tongue and lips increasing, and spreading to the upper extremities, the gait ataxic, the patellar reflex increased, or rarely, diminished, the sphincter of the bladder disordered, and there often occurs paralysis of the anal sphincters. During the progress of the second stage are developed cerebral crises, -syncope, petit or grand mal, apoplectiform attacks, or paralytic seizures. Few cases but show one or more of these conditions. There also occurs myosis and loss of light reaction, and increased wrist and elbow jerks. The maniacal stage is of shorter duration than any other, and is usually succeeded by the-

Stage of dementia, the patient presenting all the evidences of failing mentality, with paralysis, trophic changes, as shown by the occurrence of bed sores, cystitis, diarrhæa, and arthropathies, or Charcot's joints, the patient emaciating rapidly, death closing the scene within a few months.

Rarely the maniacal stage is preceded or replaced by a condition of melancholia with expansive hypochondriacal delusions. In a few instances, a genuine lucid interval has followed either the prodromal or maniacal stage. The *spinal form* of general paresis is fairly frequent, in which symptoms of spinal sclerosis are added to the mental and ataxic phenomena of the usual form.

"Of the many divisions of general paralysis into several clinical types, all of them naturally more or less arbitrary, I know no other so satisfactory as Meynert's eight " (Folsom).

1. Simple progressive dementia with the usual motor impairment

which accompanies it, but, excepting hypochondriacal depression, not necessarily exhibiting other mental symptoms than dementia.

2. With the expansive delusions and the distinctive motor disturbances which appear simultaneously and are progressive, constituting the "classic" form of general paralysis. The mental state is usually of self-satisfaction and exultation, but there may be depression.

- 3. Of the same type as the last, but failing its steadily progressive character through arrest of the active process. The remissions, which seldom last so long as a year, raise hopes of recovery, but still manifest unmistakable impairment of the reasoning faculties. The psychic disturbances are much greater than can be accounted for by the atrophy of the brain alone.
- 4. Cases in which the characteristic exultation and grand delusions reach such an astounding height that manifest motor symptoms are

looked for with confidence from day to day and yet may not appear even for a year, any slight incoördination naturally being obscured by the general muscular disturbance. Meanwhile there may be such an improvement that the patient leaves the hospital for a while, once, rarely twice, on the responsibility of his family, but to return with marked motor, as well as mental signs.

5. A very rare form, with alternate symptoms of exaltation and depression of the type of circular insanity.

6. With early furious delirium, painful hallucinations, confusion and incoherence somewhat resembling acute delirium.

7. Progressive general paralysis, in which the characteristic indications appear secondary to other forms of insanity; for instance, after paranoia or melancholia, first described by Hoestermann.

8. The combined form with sclerosis in the whole cerebro-spinal tract, the symptoms of tabes or spastic paralysis predominating, according as the posterior or lateral columns of the spinal cord are chiefly involved. The ascending type, in which the cord is first affected, is rare. Optic neuritis ending in atrophy and paralysis, especially of the ocular muscles, may precede marked mental symptoms.

Diagnosis. The development of the following symptoms removes all difficulties in diagnosis: mental—alteration in character, loss of memory, defective will power, changed moral sense, insomnia, violent impulses, melancholia or mania, unsystematized delusions of expansive character, with an exalted sense of well being, gradually ending in dementia; physical—hesitating, slurring speech, tremor of the lips, tongue, and upper extremities, pupillary changes, myosis, loss of light reaction, exaggerated wrist, elbow, and knee jerk, attacks of syncope, vertigo, epileptiform or apoplectiform seizures, ataxia, trophic changes, and finally paralysis.

Paralytic insanity, or organic dementia, is not the same condition as general paralysis. It is the form of mental failure succeeding to gross brain lesions, such as apoplexy, tumors, softening, trauma, and

sclerosis.

Prognosis. Unfavorable. Remissions very, very rarely occur.

Treatment. The care of the general health and caring for the symptoms as they arise is all that can be done for paresis. It is claimed, that if the condition be recognized early in the prodromal stage, the stage of cerebral congestion or vasomotor paresis, much good may be accomplished, and if the disease be not cured, may be

held in check for a long time, by the use of such drugs as digitalis,

ergota, or the bromides.

The maniacal excitement may be quieted by the use of the hot bath, isolation (not seclusion), and the administration of small doses of hyoscinæ hydrobromas, which seems to exert an alterative action on the brain. For the insomnia, trional, gr. xx-xxx, repeated, is usually satisfactory.

If a reliable syphilitic history is obtained, a thorough course of hydrargyrum and iodides should be administered. All means that promote the constructive metamorphosis are indicated, in this most

characteristic, progressive malady.

DISEASES OF THE SKIN.

DISORDERS OF SECRETION.

SEBORRHŒA.

Synonyms. Acne sebacea; pityriasis; tinea furfuracea; dandruff.

Definition. A functional disorder of the sebaceous glands of the skin; characterized by an excessive and abnormal secretion of sebaceous matter, forming upon the skin either as an oily coating, or in crusts and scales.

Varieties. Seborrhæa oleoso; seborrhæa sicca.

Causes. In newly-born infants an increased secretion of sebaceous matter—the *vernix caseosa*—is a physiological process.

The origin of the disease is for the most part illy understood, anæmia being a factor in many cases.

Pathology. Seborrhæa is a functional derangement of the glands; if it be allowed to become very chronic, there occurs atrophy of the glands and follicles.

Symptoms. The affection may occur upon any portion of the body, its most frequent seat being, however, the *scalp* (*seborrhæa capitis* or *pityriasis capitis*), and next in frequency the *face* (*seborrhæa faciei*).

Seborrhæa oleosa appears as an oily, greasy coating upon the skin, without hyperæmia, and not attended with itching. The secretion is of an oily character, the quantity at times being so great as to collect in minute drops of a clear, yellowish fluid upon the surface.

The most common seat for this variety is the face—seborrhwa faciei—and nose—seborrhwa nasi.

Seborrhæa sicca consists in the formation of dry, more or less greasy, masses of scales or crusts of a grayish, yellowish, or brownish-yellow color, having a strong tendency to adhere to the skin, and attended with decided itching. Occurring upon the scalp—seborrhæa capitis—it is a frequent source of premature baldness.

Diagnosis. Seborrhwa capitis may be mistaken for dry eczema, but the former is always a dry disease, while in eczema moisture has occurred at some period of the affection. The scales in seborrhœa are very abundant and pale; in eczema the scales are scanty and reddish, the parts irritated, infiltrated, and thickened.

Seborrhæa sicca and psoriasis have many points of resemblance, whether occurring on the scalp or on the body. In seborrhæa the scales are minute or caked, grayish or yellowish in color, of an unctuous feel and usually uniformly diffused. In psoriasis the scales are very dry, abundant, thick, white, irregularly dispersed, with intervening healthy skin, and the surface beneath the scales is always reddish and inflamed. The clinical histories of the diseases are entirely different.

Prognosis. If properly treated, favorable, although the affection is obstinate to eradicate.

Treatment. The secretions require attention. If anæmia be present, ferrum and arsenicum are indicated. The following formula of Sir Erasmus Wilson, and lauded by Hebra, is valuable:—

R.	Vini ferri, .					۰		٠	٠			.f Z iss	
	Syr. simplex, Liq. potassii a	arsenit	., .			āā		0				. fgij	2.7
	Aquæ destil.,											. 1 3 IJ.	Μ.
Sig	-Teaspoonful	three	tim	es a	a d	ay,	wi	th	m	ea	ls.		

Duhring recommends calcii sulphid., gr. $\frac{1}{10}$ - $\frac{1}{5}$, several times daily. Local measures are the most important in seborrhæa. For seborrhæa capitis the following plan will usually be successful:—

The scales are to be thoroughly moistened with either oleium oliva,

oleum morrhuæ or adeps, to facilitate their removal; it is best applied at night and the head covered with a flannel or other cap. As soon as the crusts are well soaked they should be removed by washing with soap and warm water, or equal parts of soap, glycerine, and water, or the following will be found valuable:—

Sig.—Dilute and use as a soap wash or shampoo.

The scalp is to be thoroughly cleansed of either of the above by again washing with warm water and then dried by means of soft towels. Then should be applied some oily or fatty substance, depending upon the condition of the scalp.

If much irritation, either vaseline or oleum amygdale expressum. If no irritation be present, a stimulating preparation will be found of great benefit. Either of the following may be used:—

R. Tinct. cantharidis,	
Tinct. capsici, f	
Ol. ricini, f	Z ij
Alcoholis, f	3 ij
Spt. rosmarini,	f 3 j. M.
	-DUHRING.
Or,	
R. Bismuthi subnitratis,	3 i
Ung. hydrargyri ammon.,	Z ij-iv.
Ung. aquæ rosæ, ad	ξj. Μ.

The above should be repeated every day or two, as the symptoms may require, until a cure is effected.

The following combination is useful for dandruff:-

R.	Ammonii muriat.,			۰		٠	٠	٠						gr. x'l	
	Glycerinæ,	-	٠		٠	٠	•	٠	۰	٠	٠	•"	٠	f℥j	3.6
Sig.	Aq. rosæ,	0	۰	۰	•		۰	٠	٠	•	٠	۰	*	13 v.	M.

The seborrhœa of other portions of the body are to be treated upon the same general principles.

COMEDO.

Synonyms. Acne punctata nigra; black-heads or worms.

Definition. A disorder of the sebaceous glands; characterized by retention in the excretory ducts of an inspissated secretion which is visible upon the surface as yellowish or whitish pin-point and pin-head-sized elevations, containing in their centre blackish points.

Causes. The true etiology is unknown. Among the causes assigned are anæmia, menstrual disorders, urethral irritations, dyspepsia, and constipation.

Pathology. Comedo is an affection of the sebaceous glands and ducts, consisting of an accumulation of sebum and epithelial cells in the glands and follicles, dilating the ducts to such an extent as to produce the point or elevation upon the surface. The obstructed gland may relieve itself, or it may continue distending until a papule is formed. The duct sometimes contains small hairs, and also the microscopic mite—demodex folliculorum—having a length of from $\frac{1}{150}$ to $\frac{1}{75}$ of an inch, and breadth of about $\frac{1}{500}$ of an inch, which was at one time erroneously supposed to be the cause of the affection.

Symptoms. Essentially a chronic affection, observed for the most part on the face, neck, chest, and back. Each single elevation or black-head or point is designated a *comedo*, or if a number, in the plural, as *comedones*.

Each comedo is small, varying from a pin-point to a pin-head in size, having a brownish or blackish appearance, from the dust or dirt that has adhered to their unctuous surface. If they form in great numbers upon the face they are disfiguring, giving the individual the appearance of having had minute grains of powder implanted in the skin. There are no evidences of inflammation unless acne is associated, but, on the contrary, the skin has a dirty, greasy, unwashed appearance.

Diagnosis. There is no condition resembling comedo, so that its recognition is easy, unless complicated with acne; but even then the inflammatory appearance of acne should prevent an error.

Prognosis. Favorable, although often remarkably obstinate.

Treatment. Derangements of any of the functions of the body should be corrected, and strict attention be given to the rules for promoting the general health.

Local measures are usually sufficient to promote a cure of the affection.

The parts affected should be thoroughly softened by bathing with soap and warm water, when the comedones are removed by friction with a Turkish towel, pressure between the thumb nails, the application of a watch key, or the instrument known as the "comedo extractor," and their return prevented by an unguentum medicated, to meet the indications, with either sulphur, alkalies, or hydrargyrum.

Dr. Shoemaker recommends the following formula:-

В.	Thym	ol, .											gr, x	
	Acidi	borici,											3 ij	
	Aquæ	hamar	nel. '	Virg.	dest	٠,							f Z iv	
	Aquæ	rosæ,									٠		ſ℥j.	M.
Sig.	-Мор	well o	ver t	he su	rface	or	ice	or	tw	ice	da	aily	7.	

MILIUM.

Synonyms. Grutum; tubercula miliaria or sebacea; acne punctata albida.

Definition. An accumulation of sebum in the sebaceous glands which are minus their excretory ducts; characterized by the formation of small, roundish, whitish, sebaceous, non-inflammatory elevations, situated immediately beneath the epidermis.

Cause. The origin of the affection is not understood.

Pathology. The sebaceous gland is distended with the sebum, which is unable to escape, owing to the obliteration of the duct, nor can the contents be squeezed out, as no sign of aperture is to be found, the formation being completely enclosed.

Rarely the retained secretion undergoes a metamorphosis into hard, calcareous, stone-like masses—sebaceous concretions or *cutaneous calculi*.

Symptoms. Milia may occur upon any portion of the body; their usual seat, however, is upon the face, forehead, and about the eyes. They form gradually, are about the size of a millet seed, of a whitish, pearl, or yellowish color, hard, and of a rounded shape, giving the sensation to the touch of hard bodies embedded in the skin. They are not associated with inflammatory symptoms.

Diagnosis. Milium and comedo are somewhat similar in appearance; the differences are that in milium the sebaceous gland is

distended without an opening, while in comedo the duct of the gland is always patulous upon the surface. Milium usually exists singly, the skin looking normal; while comedo is more general, the surface having a soiled and greasy appearance.

Prognosis. Favorable.

Treatment. As a rule, no treatment is needed, the number being few and their presence of no consequence.

If their removal be desirable, two modes suggest themselves: one, to open the cyst with a fine-bladed bistoury, and turning the contents out, destroying the remaining sack by the application of either tinctura iodi, or acidum chromici; or, the cyst may be destroyed by electrolysis. If a tendency to recur is shown, the plan may be repeated.

SEBACEOUS CYST.

Synonyms. Wen; sebaceous tumor; encysted tumor.

Definition. A distention of the sebaceous gland and duct, with hypertrophy of the walls, which forms a thick, tough sack or cyst; characterized by the appearance of a firm or soft, more or less rounded tumor, having its seat in the skin or subcutaneous connective tissue.

Cause. Unknown.

Pathology. Hypertrophy of the gland and duct walls, the result of pressure from the accumulated contents, which consist of the altered products of the sebaceous secretion.

Symptoms. The development of wens is slow and insidious. The localities where they are more commonly developed are the scalp, face, back, and scrotum.

The tumors occur singly or in numbers, in size from a pea to a walnut, or larger, in shape either rounded, flattened, or semi-globular; in consistency they are either hard or soft, and doughy; they are freely movable and painless.

Diagnosis. Sebaceous cysts may be confounded with fatty tumors.

Treatment. Excision and careful and thorough dissection of the cyst.

HYPERIDROSIS.

Synonyms. Hydrosis; ephidrosis; excessive sweating.

Definition. A functional disorder of the sweat glands; characterized by an increased secretion of sweat. The sweating may be either general or partial.

Causes. Often undetermined; occasionally inherited; nervous derangements; malaria; diseases of the heart and lungs.

Pathology. A functional derangement of the sudoriparous glands, over which the vaso-motor system has control. The character of the secretion, chemically, may not differ from the normal.

Symptoms. Universal general sweating, such as occurs during the course of pneumonia, rheumatism, tuberculosis, typhoid and other febrile maladies, can hardly be considered a distinct affection.

Hyperidrosis may be acute or chronic, the amount slight or large, being constant or paroxysmal, the extent general or local, and it may or may not be symmetrical.

Bromidrosis is the designation when the secretion has an offensive odor.

Chromidrosis is the designation when the fluid poured forth is variously colored.

Uridrosis is the designation when the excretion from the sweat glands contains the elements of the urine and particularly urea.

Phosphoridrosis is the designation when the perspiration appears luminous in the dark.

Local hyperidrosis occurs most commonly upon the palms, soles, axilla, and genitalia.

Hyperidrosis of the palms may be so profuse that the fluid accumulates and keeps the parts constantly macerated, the wearing of gloves being impossible, for as soon as the parts are wiped dry they are again bathed in the secretion. Jamieson states that hyperidrosis of the hands is very common in those who are daily excessive spirit drinkers; this is not my experience.

Hyperidrosis of the soles is a disagreeable and often distressing condition, as the socks and shoes become saturated, and thus keep the soles constantly bathed, allowing the macerated epidermis to peel off, leaving a more tender skin exposed, causing pain and distress when walking. The maceration of the epidermis, the secretion about the toes, together with the moisture of the socks and the soles of the shoes, promote the rapid development of the bacteria fatidum; all these together produce a most disagreeable, disgusting, and persistent odor, which is termed bromidrosis pedum.

Hyperidrosis of the genitalia attacks males more particularly, giving rise to a disagreeable, penetrating odor.

The sweating may be limited to one side—unilateral hyperidrosis.

Prognosis. The majority of cases are extremely intractable; complete recovery is rare in a fair proportion, while some cases are easily relieved.

Treatment. The general condition of the patient must receive proper attention.

Local treatment is the most valuable, however, in this affection.

The parts should be cleansed and immediately dried, and then dusted with some one of the numerous dusting powders. The following is a valuable powder:—

Perhaps the very best local application is *tinctura belladonnæ*, either diluted or full strength. *Aristol* as a dusting powder is very satisfactory.

In hyperidrosis of the palms and soles, the following are valuable, first washing the parts with a weak solution of acidum carbolicum:—

	ıx .	Cretæ præp.,			۰	•	۰	۰	۰	•	*	٠	•	٠	3 ss	
		Aluminis exsic.,		۰	٠	٠		•	۰	•		•	•	٠	2	
	M	. et powder finely			•	٠	٠	٠	٠	•	•	•		٠	5J.	
					.cc	h	11									
	SIG.	—Apply to parts v	VILL	ı þi	III	Da	11.									
Or—																
	R.	Acid. salicylici,													2 parts	
	2,00	Pulv. amyli, .							Ť			•	•	٠	IO parts

	R.	Sulphur. lotum.,													or xxx	
	1,0	Pulv. arrowroot,			Ĭ						Ť	Ü	Ü	Ů	7 iv	
		Acid salicylici,														M.
	~									٠	۰	•		۰	g1. v1).	TAT *
	SIG.	—Dust over feet a	ind	be	tw	eer	a t	oes	5.							
Or—																
	R	Potassii permang	ana	1											ar ii	
	17	Aque destil														M

A saturated solution of *acidum boracicum* applied frequently to the hands and feet often proves curative.

For obstinate cases, involving the palms or soles, the following plan of treatment, as suggested by Hebra, will be found of the greatest service. It is imperative that the various steps be closely followed:

R Acidi saliculici

"The parts are to be cleansed with water and soap, and the following ointment applied on pieces of cloth cut to the size of the region. Lint smeared with the ointment is also to be placed between the toes or fingers, so that every portion of the skin may be covered with a layer of the ointment.

The plaster to be melted, and the oil added and stirred until a homogeneous mass results.

Sig.—To be used on cloths.

"The cloths are to be changed every twelve hours, when the parts are not to be washed, but rubbed with dry lint and starch dusting powder, after which new dressings are again to be applied in the same manner. This proceeding is to be continued from one to two weeks. When the disease is upon the soles, the patient may walk about in loose shoes." After a week or ten days the ointment can be discontinued, but the dusting powder is to be continued for a considerable period. If relapses occur, the original treatment should again be instituted.

SUDAMINA.

Synonyms. Sudamen; miliaria crystallina (Hebra).

Definition. A non-inflammatory affection of the sweat glands; characterized by the rapid development of millet-seed-sized, translucent, whitish vesicles, in great numbers, upon any portion of the body.

Causes. A high temperature, causing unusual activity of the sudoriparous glands.

Pathology. The glands being excited beyond their capacity for normal excretion, the excessive fluid, instead of escaping upon the surface, from some cause collects between the layers of the epidermis, in the form of minute, translucent, pin-point-sized vesicles.

Symptoms. Each minute vesicle is distinct, but they exist in great numbers, very closely resembling drops of free sweat. They develop rapidly, never coalesce, become puriform, or rupture. Fresh crops form from time to time. Their duration is transitory; the fluid is absorbed, the covering of each dries, forming a thin, delicate membrane, which disappears as a slight desquamation.

Treatment. The treatment is that of the disease with which they occur.

ANIDROSIS.

Definition. A functional disorder of the sweat glands; characterized by a diminished or insufficient secretion of sweat.

Cause. The result of a congenital deficiency of the sweat glandular apparatus. Local anidrosis may result from injury to a nerve, during the course of chronic diseases of the skin, as ichthyosis, eczema, psoriasis, lepra, and elephantiasis arabum. In rare cases an individual ceases to sweat entirely at times; in such cases the general health is impaired, and during the hot season much suffering may ensue.

Treatment. Means to promote the activity of the skin and glands is the indication, such as the ingestion of large quantities of water, hot baths and steam baths, friction, and the use of sudorifics, the most valuable of which is *pilocarpus*.

HYPERÆMIAS OF THE SKIN.

ERYTHEMA SIMPLEX.

Definition. An acute affection of the skin, in which occurs an abnormal quantity of blood in the dermal vessels; characterized by discoloration, which disappears upon pressure and with more or less local increase of temperature.

Varieties. Idiopathic erythema; symptomatic erythema.

Causes. *Idiopathic erythema*; heat, cold, pressure, friction, or the contact of irritants, such as mustard, arnica, and dyestuffs.

Symptomatic erythema occurs most frequently in childhood, from diseases of the stomach and intestines; during the course of the various exanthemata.

Symptoms. A more or less rapidly developed redness of the skin, varying in color from pink or light red to dark red, which disappears upon pressure, to rapidly return again. The extent and form of the congestion varies according to the cause, at times being as small as a coin and isolated, and again diffused over a large area. The temperature of the congested part is slightly above the normal. Slight itching and burning are, usually, associated with the discoloration.

Diagnosis. Erythema resembles acute dermatitis in color, but

the subjective symptoms of the latter are so decided that an error should not occur.

Treatment. Controlled by the cause, which should be removed, and the local application of some one of the various dusting powders.

ERYTHEMA INTERTRIGO.

Definition. An acute congestion of the skin; characterized by redness, heat, increased perspiration, and an abraded surface, with maceration of the epidermis.

Causes. In the fleshy, from contact or friction of opposing surfaces exposed to warmth—chafing. In children and infants contact

of moist clothing; also disorders of digestion.

Symptoms. Parts where the natural folds of the skin come in contact with one another, as the nates, perineum, groins, axillæ, and beneath the mammæ, in the fleshy and in infants, become red, hot, painful, and have an increased flow of perspiration, which in turn softens the epidermis, giving rise to an acrid, mucoid fluid. If not checked by the removal of the cause and the application of the dusting powders, inflammation—dermatitis—results.

Treatment. The congested parts should be thoroughly washed with water and castile soap, or with bran-water, and carefully dried with a soft towel. The opposing folds of the skin are to be kept separated with lint or soft linen, the parts first covered with cretæ præparata, zinci oxidum, bismuthi subnitras, amylum, lycopodium, or buckwheat flour.

INFLAMMATIONS OF THE SKIN.

ECZEMA.

Synonyms. Tetter; salt rheum; scall.

Definition. A non-contagious inflammation of the skin, characterized by any or all of the results of inflammation, at once, or in succession, such as erythema, papules, vesicles or pustules, accompanied by more or less infiltration and itching, terminating in a serous discharge, with the formation of crusts, or in desquamation.

Forms. Acute; chronic.

Varieties. Eczema crythematosum; eczema vesiculosum; eczema

papulosum; eczema pustulosum; eczema rubrum; eczema squamosum; eczema fissum; eczema verrucosum; eczema sclerosum.

Causes. Eczema attacks persons in all spheres, the rich, the poor, the infant or the aged, and males or females. Many families, especially those having the "catarrhal predisposition or peculiarity of constitution," seem more liable; indeed, it appears probable that a predisposition to eczema may be transmitted from parent to child. Among the causes suggested are; dentition, improper food, gastrointestinal disorders, intestinal parasites, deficient urinary secretion, the rheumatic and gouty diathesis, vaccination, prolonged contact of hot fomentations, heat and cold, and contact with the poison vine, (rhus toxicodendron), and poison tree, (rhus venenata).

Pathology. Eczema is a catarrhal inflammation of the skina dermatitis, with superficial serous exudation. There is first hyperamia or congestion of the vessels of the skin-eczema erythematosum when uniformly distributed, eczema papulosum, when the congestion is limited to distinct points. The hyperæmia is soon followed by a serous exudation. If the superficial exudation be profuse enough to form small drops, and if the epidermis possess sufficient resisting power not to give away immediately before it, vesicles form, producing the variety known as eczema vesiculosum; if the vesicles contain a large admixture of young cells, so that the serum be turbid, yellow and purulent, the vesicles become pustules, termed eczema pustulosum: if the serous exudation be not sufficient to either elevate or break through the epidermis, instead of either vesicles or pustules forming there occur dry scales, rising from the reddened skin-eczema squamosum. When the exudation is sufficient to detach the epidermis, thus exposing the red and moist corium, it is termed eczema rubrum.

In chronic eczema the skin is subacutely inflamed; is very much thickened, hardened, and infiltrated with cells which extend throughout the entire corium, even into the subcutaneous connective tissue. The papillæ are enlarged, and at times, may be distinguished with the naked eye. Pigmentation may take place in the deep layers of the rete, and in the corium, especially about the vessels.

Symptoms. Eczema is the most common of all cutaneous affections, with symptoms varying in accordance with the particular variety of the affection and its location, although the general characteristics of a catarrhal inflammation are present in all; these are *redness*,

either limited or diffused; heat, of the part affected; swelling, the result of the serous exudation, giving rise either to a discharge (weeping), with subsequent crusting, or to the deposition of plastic material. The most constant, annoying, and troublesome symptom is the itching, or at times burning, which varies from that which is simply annoying to that which is almost unendurable.

Eczema runs its course either as an acute affection, lasting a few weeks, not to return, or to return acutely at wide intervals, or, as is much more frequently the case, it assumes a chronic state, continuing with more or less variations for months, years, or even a lifetime. It may appear upon any portion of the body, or involve the whole integument (eczema universale). The varieties are named in the order which the lesions assume at their commencement.

Eczema Erythematosum. An erythema or redness of the surface, with a yellow tinge. The size of the macule may be very small or quite extensive, with irregular outlines. There may be slight swelling of the patch, but no discharge occurs unless it be where two surfaces come into contact, (eczema intertrigo), as about the genitalia. Cases without discharge are covered after a few days with a thin film of dry, exfoliating epidermis or scale (eczema squamosum). When a discharge (weeping) or moisture occurs, it is followed with more or less crusting.

Intense itching is a constant symptom.

Eczema Papulosum, or Lichen Simplex. This variety of eczema appears in the form of small, rounded papules, the size of a pin-head, of bright red, or at times dark red color; they may be either discrete or confluent. In some cases all, while in others a greater or less number, of the papules pass into vesicles and run much the same course as vesicular eczema. The itching is of the most intense character, leading to severe scratching, by which the summits of the papules are torn, causing them to bleed, the blood forming dark red crusts.

Eczema Vesiculosum. Begins with burning, pain, redness, and swelling, followed by an immense number of minute vesicles, either discrete or confluent, rapidly distending with a clear or yellowish fluid and attended with intense itching. Soon the vesicles rupture, the fluid rapidly diffusing over the surface and drying into yellowish, honey-like crusts. New crops of vesicles soon follow, or if subsequent vesications do not occur, the fluid rapidly diffuses over the excoriated

surface, which also, in turn, dries into large, yellowish crusts. After a variable time the various symptoms gradually subside.

Itching is the most prominent subjective symptom, is intense, and gives rise to an irresistible desire to scratch.

All portions of the body are liable to this variety of eczema, the most frequent location, however, being the face, and when occurring in children is commonly known as *crusta lactea*.

Eczema Pustulosum, or Eczema Impetiginosum. This variety usually begins as vesicular eczema, the fluid rapidly changing to pus. After a short period, during which the pustules have increased in size, they burst and the escaped fluid forms thick, greenish-yellow crusts, which, in turn, rapidly dry and fall off, or crumble away.

The location of this variety is most usually upon the scalp and face. It is stubborn to treatment. *Itching* is a prominent symptom.

Eczema Rubrum, or Eczema Madidans. This is a variety only from a clinical standpoint. It may result from any of the foregoing varieties. The surface of the skin is inflamed and infiltrated, red, moist, and weeping, the profuse serum rapidly drying into thick, yellowish, greenish, or brownish crusts, the color depending upon the character of the fluid, which may be serum, pus, or blood from the exposed and lacerated corium. The crusts adhere closely and firmly to the part, and, unless removed by mechanical means, may remain indefinitely, the disease pursuing its course beneath. Eczema rubrum, or madidans, "then, presents two appearances—as it occurs with its crust, and as it exists without this covering. In the one case the skin itself is altogether obscured by a dirty, yellowish, or brownish crust; in the other the skin presents a bright or violaceous red, punctate, wounded surface, deprived in great part of its epidermis, and exuding a scanty or profuse, clear or opaque, syrupy, yellowish fluid. Sometimes this is streaked with blood." The itching and burning are severe. It may develop upon any portion of the body, but is most commonly seen upon the legs, particularly in elderly people. Its course is chronic and increasing in severity.

Eczema Squamosum. This is also a clinical variety. It results from the erythematous, vesicular, pustular, or papular varieties of the affection, but more particularly the first named. A typical case presents itself in the form of variously sized and shaped reddish patches, which are dry, or more or less scaly, the skin being more or less infiltrated or thickened. Its course is usually chronic.

Eczema Fissum, or Rimosum. Another clinical variety. During the progress of the erythematous, vesicular, or pustular varieties of eczema, cracks or fissures result when the lesion occurs upon regions subject to constant motion, such as between the fingers, toes, and the various joints. At times the fissures are extensive and deep and of a bright red color, showing the true skin, and intensely painful upon motion. Chapped hands are typical instances of fissured eczema.

Eczema Sclerosum. This variety of eczema, occurring most commonly on the palms, soles, and finger tips, is characterized by hypertrophy of the papillæ, showing itself as hard, thickened, infiltrated, localized patches, which are most apt to crack (eczema fissum).

Eczema Verrucosum, or Papillomatosum, differs from the foregoing in that the thickened, infiltrated patch has a warty verrucous appearance. Its course is chronic.

Eczema Acutum et chronicum. The line which divides these two conditions is drawn by means of the clinical and pathological features. The course of eczema, in the majority of instances, is chronic. It may be said that so long as the general inflammatory symptoms are high and the secondary changes slight, the affection is acute, and that when the process has settled itself into a definite line of action, continually repeating itself and accompanied by secondary changes, it is chronic.

Diagnosis. The many varieties in which eczema manifests itself renders the diagnosis a matter of importance. The following characteristic features of eczema are of value in arriving at a diagnosis: inflammation, swelling and adema, thickening from cell infiltration, redness, the discharge or moisture, followed by crusting, on removal of which a moist surface is presented, and itching and burning.

Erysipelas may be confounded with erythematous or vesicular eczema. The points of difference are the fever and other general disturbances. The deep-seated inflammation of the skin, rapidly spreading with heat, swelling and cedema without moisture, giving the surface a deep red, shining, and tense appearance, are characteristic of erysipelas and very different from eczema.

Herpes and vesicular eczema bear some resemblance to each other; herpes zoster is distinguished by the neuralgic pains which are associated with it and are never associated with eczema. The other varieties of herpes occurring about the face and genitalia run their course

in a few days, while eczema is of much longer duration and has a discharge followed by crusting.

Seborrhæa of the scalp and squamous eczema of the same region closely resemble each other. In eczema, however, the skin is more or less red, inflamed, and thickened, and the scales larger, less abundant, and less greasy and drier than seborrhæa. In eczema the scales are usually seated upon a circumscribed patch, while in seborrhæa, as a rule, they cover the scalp uniformly. Itching occurs with both disorders. The history of the two affections should be of material aid to render the diagnosis clear; still, however, in many cases the difficulty is marked. Both are frequent affections.

Psoriasis should never be confounded with a typical case of eczema, but chronic eczema, with infiltrated, inflammatory, scaly patches, frequently looks very much like psoriasis.

Treatment. There is no specific. The indications are for the removal of the cause, where it can be ascertained, if it be possible, and attention to the general health. The diet should be of the most nutritious, but easily digestible character; fresh air and moderate exercise are also essential elements in the treatment, together with attention to the secretions. If the bowels be sluggish, much benefit follows the use of such laxative mineral spring waters as the Hathorn, or Hunyadi Arpad, or a morning dose of magnesii sulphas. For children, syrupus rhei, to which may be added magnesia; or, what is perhaps more efficient, a small dose of hydrargyri chloridum mite. If the urinary secretion be small and the urine heavy, use should be made of full doses of potassii acetas, and large draughts of water. If either a rheumatic or gouty disposition exist, lithium salts, to which may be added vinum colchici seminis. If a scrofulous tendency exist, use oleum morrhuæ and syrupus ferri iodidi. If anæmia, ferrum, quinina, strychnina, and the mineral acids, or syrupus hypophosphitis comp., are indicated.

Locally: the most important means of treatment for all the varieties of eczema are with local remedies, suiting the appropriate ones for each particular case, as no one combination is applicable for all varieties. It may be stated, as a principle, that nothing irritant is ever to be applied to the surface in acute eczema, and that in the chronic form nothing can hardly be too stimulating. The too frequent washing or general baths are to be avoided, as they have a tendency to

macerate the already softened epidermis. For cleansing purposes, in the majority of instances, ordinary Castile soap is sufficient.

Crusts and scales are nearly always present in eczema, and are to be removed before medicaments can be successfully applied. Their removal is to be secured by saturation with oily preparations, a starch or other mild poultice, or a saturated solution of acidum boricum. After their removal the parts are to be cleansed with Castile soap and water.

For acute *erythematous* or *vesicular eczema*, use but little, or what is better, no, soap or water; instead, cover the parts with a dusting powder, one of the most useful being *Acidum boricum*, or

R.	Pulv. ca	mpho	ræ	,													3j	
	Zinci ol	eat.,	۰		٠	٠	٠				٠	٠	٠	٠	٠	٠	3 ij	3.6
	Pulv. ar Dustin				. *	٠	٠	٠	٠	٠	•	•	۰	٠	٠		3).	M.

For acute vesicular eczema, Dr. J. C. White recommends bathing the affected part with lotio nigra (hydrargyri chlor. mite gr. viij, liquor calcis f3j), full strength, or diluted with equal parts of limewater, applied by means of a sponge or a piece of cloth, for ten or fifteen minutes at a time, and at intervals of a few hours or longer, the sediment being allowed to remain on the skin; after which ung. zinci oxid. is to be gently rubbed over the part. As a rule, the itching and burning are relieved at once, and the affection often arrested. Good results follow the use of a saturated solution of acidum boracicum.

There are cases which do better from the application of ointments, of which the following is valuable:—

Ŗ.	Zinci oleat.,													
	Olei olivæ,		٠	٠	٠	٠	٠	āā	٠	٠	٠	٠	3 iv.	M.

Or, bismuth oleate, made according to the following formula of Dr. McCall Anderson:—

R.	Bismuthi oxidi,					۰				<i>3</i> j
	Acidi oleici, .			٠						3)
	Ceræ albæ,				۰					Z iij
	Vaselini,		٠							Zix

M.

If the discharge be excessive, the following formula of Prof. Bartholow I have seen useful:—

R .	Plumbi acetat., .								Z ss	
	Pulv. camphoræ,						٠		gr. xv	
	Ol. amygdal., .				۰				fžij	
	Cerat. flav.,									M.

The late Dr. Frank Maury was partial to the following formula in vesicular eczema:—

For eczema papulosum the following lotions are particularly valuable:—

R .	Acid. carbolic	i,	٠					٠		٠			• _3 j–ij	
	Glycerini, .													
	Alcoholis, .													
	Aquæ destil.,	٠	•	۰	٠	٠	٠	۰	۰	ad	*	۰	. Oj. —Duhring.	Μ.
Ŗ.	Thymol, .				٠				٠	٠		٠	. gr. x-xx	

Or-

eczema.

After the disappearance of the more acute symptoms, more stimulating applications are indicated, among which are acidum carbolicum, thymol, pix liquida, or oleum cadinum. It is to be remembered, however, that the more chronic the affection and the less the inflammatory symptoms, the more successful is tar in the treatment of

Aquæ destil., f ž j.

Dr. Duhring considers the following one of the most elegant of the tarry ointments:—

R. Olei cadini, f z iss

The following is Dr. Bulkley's valuable "liquor picis alkalinus:"-

R.	Picis liquidæ,	٠							fgij	
	Potassæ causticæ,		٠			٠	٠		31	2.5
	Aquæ destillatæ,	٠						٠	13 v.	M.

The potassa to be dissolved in water and gradually added to the tar with rubbing in a mortar.

Sig .- To be used diluted.

A very elegant preparation of tar is the French mixture known as "Goudron de Guyot."

For eczema rubrum, one of the most intractable varieties of the disease, especially the chronic eczema of the legs, the following mode of treatment, first suggested by Hebra, is the treatment par excellence.

The accompanying instructions are to be adhered to. A lump of the sapo viridis (made originally of herring fat and potassa, and containing three per cent. of caustic potassa), the size of a small nut, is smeared upon a piece of wet flannel and applied to the affected part, and firmly rubbed until the soap has disappeared, when the flannel is to be dipped into warm water and again applied to the part and rubbed until an abundant lather forms, more water being added from time to time until the suds are most abundant, when the surface is thoroughly washed and freed from all the soap and carefully dried, after which the following (Hebra's diachylon) ointment, having been spread before the application of the soap, is to be applied. It is prepared as follows:—

"Fifteen ounces of the best olive oil are added to two pounds of water, and heated to boiling in the water bath. Three ounces and six drachms of an equally good article of litharge (plumbi oxidum) are dusted over the fluid in ebullition, which is constantly stirred throughout, in order to prevent the formation of fatty acids. During the cooking, water is occasionally added as required. The stirring is to be continued until the ointment is quite cold."

The ointment is spread upon strips of soft muslin and the affected part enveloped, care being exercised that neither folds nor wrinkles occur, the whole being covered by a firm roller and the patient being able to go about as usual. The entire operation is to be repeated twice daily.

A modification of the above ointment, technically known as "un-

guentum diachyli albi of Hebra," has been successful in my hands in a number of cases. The formula is:—

Prof. Da Costa has used with success in eczema rubra, liquor arsenici et hydrargyri iodidi, mij-v, after meals, and—

An excellent formula in eczema of the vulva is :--

Eczema capitis is either erythematous, vesicular, or pustular in character. If the first named, it at once tends to become chronic, settling into the variety known as eczema squamosum, often involving the entire scalp and accompanied with intense itching. The pustular variety is the more common form, occurring upon the scalp of children and young adults, existing as a few patches, or, what is more frequent, involving the entire scalp. The pustules soon rupture, the liquid drying into greenish-yellow crusts, which, if the affection be extensive, cover the whole scalp with a cap of crust. The hair becomes matted and caked, the sebaceous secretions collect, and if the part be not cleansed the head becomes offensive. In severe cases of pustular eczema of the scalp, enlargement of the lymphatic glands of the back of the neck and of those behind the ear occur; they never suppurate. Pediculi are frequently associated with eczema capitis of children, either as a primary cause or a result of the matted condition of the hair constituting a favorable habitat for them. When present they call for active treatment.

Eczema capitis may be confounded with psoriasis, seborrhœa, syphilis, tinea favosa, and tinea tonsurans.

Treatment. If the pustular variety, removal of the crusts is the first indication. This is accomplished by saturating the scalp either with oleum olivæ or oleum amygdalæ dulcis, and then washing with warm water and soap, or the use of a starch poultice or a twenty-five per centum solution of boroglyceride; after their removal the application of the following ointment, recommended by Prof. Da Costa:—

Ŗ.	Hydrargyri chlor. mitis.,							
	Acid. carbol. cryst.,	٠					gr. iij.	
	Ung. petrolei,						Зj.	M.
Sig.	-Thoroughly applied.							

The late Prof. Ellerslie Wallace was fond of the following:-

R.	carb., . petrolei,							gr. xxx. Zi.	M.
Sig	 y thoroug							0.	

I have usually been successful with cleanliness, proper dietary, the internal use of *liquor arsenici et hydrargyri iodidi*, mss-j, well diluted, after meals, and the local use of acidum boricum, or ung. zinci oxidi to which has been added a few drops of acidum carbolicum.

In cases associated with *pediculi*, I have succeeded with the following, after removal of the crusts:—

Ŗ.	Hydrargyri ammoniat.,	۰	٠	٠			٠			gr. x-xx.	
	Adeps benzoat.,	٠	٠	۰	۰	٠	٠	0	٠	3 j.	M.
Sig	-Thoroughly applied.										

For the squamous variety of the scalp, the following formula, recommended by Dr. Duhring, is excellent:—

R.	Picis liquidæ,			٠											fʒj.	
	Glycerini, .															
	Alcoholis, .															2.6
	Ol. amygdalæ	an	ıar.,	٠	٠	۰			٠	٠	٠		٠	٠	gtt. xv.	Μ.
SIG -	_Diluted or fu	11 9	tren	oth	1	rnh	he	b	the	orc	1110	hl	v	int	o scalp.	

Eczema faciei. In this location the affection may be either acute or chronic. In adults the erythematous variety is frequently encountered in patches about the forehead and cheeks. Eczema of the face is more common in children, however, the varieties being the vesicu-

lar and pustular. It is seen on the forehead, nose, and upper lip, and is associated with severe itching.

Treatment. The same as eczema capitis, or the following:-

Eczema labiorum. Eczema attacks the lips, either alone or in connection with other parts of the face. One or both lips may be affected. The symptoms are: swelling, redness, heat, infiltration, slight scaliness, and fissures. The affection may be in the skin around the border of the mouth, or the vermilion and mucous membrane of the lips. The mouth may be contracted and the lips partly glued together by the exudation and crusts.

Eczema labiorum may be confounded with herpes labialis and syphilis.

Treatment. Very difficult and discomforting to the patient. Among the remedies at times successful are: argenti nitras, potassa nitras, acidum carbolicum, pix liquida, oleum ergota, and collodium flexile.

Eczema palpebrarum. A frequent occurrence in scrofulous children, showing itself along the edges of the eyelids. Pustules involve the hair follicles, followed by the usual crusting. The symptoms are swelling, redness, and itching, and unless the parts are frequently cleansed, the lids tend to glue together. Conjunctivitis frequently complicates the affection.

Treatment. In mild cases success follows the use of zinci oleat, or glyceritum acidi tannici. In severe cases the plan recommended by McCall Anderson should be pursued. It consists in the extraction of the eyelashes and touching the edges of the lids with a solution of potassa in water, ten grains to the ounce. The edges should be carefully dried and the lid everted, a very small quantity on a delicate brush being applied, immediately neutralizing the alkali with acidum aceticum or vinegar.

Eczema barba. Eczema of the beard is characterized by the formation of extensive pustules, with preference for about the hairs, drying as yellowish or greenish crusts, matting the hairs together and adhering to the parts. The affection may be confined to the hairy portions of the face, or extend to other regions of the face, be localized or general, acute or chronic.

Eczema barbæ in general features somewhat resembles both tinea

sycosis and sycosis non-parasitica, but sycosis is an inflammation of the hair follicles only and is rarely associated with crusting, while crusting is abundant in eczema.

Treatment. Must be energetic and decided. The crusts are to be removed by poultice or warm water and soap. Then the part is to be cautiously shaved; although quite painful the first time, it is hardly so afterward, as it is to be repeated every two or three days. After shaving, if the attack be acute, the same plan of medication as recommended by Hebra for eczema rubrum is to be practised, the application to be continuous both day and night, or only at night. If the attack be chronic, the following ointment should be applied after cleansing and shaving the beard:—

In this variety of eczema I have seen marked benefit from the use of *liquor arsenici et hydrargyri iodidi*, mjj-v, three or four times daily.

Eczema aurium. Eczema of the ears may be either erythematous, vesicular, or pustular. If the former, thickening results, with desquamation of flakes or large scales; if either of the latter, crusts form, which may envelop the whole ear, the symptoms being swelling, redness, and severe burning and itching, and if the process extend into the meatus, occlusion may result, causing temporary deafness. The most characteristic symptoms of erythematous eczema of the external auditory canal, besides the appearance of small flakes, is intense and persistent itching.

Treatment. For acute vesicular or pustular eczema, removal of the crusts and the use of hydrargyri chloridi mite as an ointment of the strength of thirty grains to the ounce. If chronic, the use of pix liquida, as already suggested. For chronic erythematous eczema of the external auditory canal, the following formula has generally controlled this stubborn condition:—

R.	Hydrargyri flav. oxid.,						۰			gr. j–iij	
	Morphinæ sulph.,	٠	٠	٠			٠		٠	gr. j	
	Vaseline,	•		۰	٠	٠	•	٠	۰	3 ^{ij}	M.

Eczema genitalium. This is a most distressing condition. In the male the scrotum and penis are involved alone or together, the former

alone being the more common, and is complicated with eczema of the inner side of the thigh or thighs. The symptoms of eczema of the scrotum are, swelling, often ædema as well, moisture, crusts, and painful fissures, followed by extensive thickening and accompanied by intense itching. In the female the affection attacks the labiæ, and, rarely, the vagina and mons veneris, and may extend to the surrounding parts, especially to the perineum. The symptoms of eczema of the labia are, great swelling, ædema, redness, with great heat and a free discharge, forming crusts, which are apt to glue the opposing surfaces together. If the variety be the erythematous, in place of a discharge with crusts, the symptoms named are followed by slight scales. The itching is most violent and distressing.

Treatment. The parts attacked should be kept constantly enveloped in cloths wet with a saturated solution of acidum boricum until the more pronounced inflammatory symptoms subside, when the acidum boricum may be used as a dusting powder, completely enveloping the parts. Mild solutions of menthol are valuable. Tinctura myrrh, well diluted, is an excellent application. Ointments of zinci oleat. or hydrargyri chloridum mile are sometimes valuable. Persistent cases will often succumb to the plan of treatment suggested by Hebra for eczema rubrum.

Eczema ani. The anus may be attacked alone or associated with eczema of the perineum and genitalia. The symptoms are: redness, swelling, infiltration and thickening, with or without fluid exudation. Fissures of the anus are usually present, and add to the distress of the patient, severe pain attending each stool. Persistent itching and burning, worse after retiring, adds to the misery of the patient.

Pruritus ani may be mistaken for eczema ani. In the former the itching is only associated with such symptoms of inflammation as result from the irritation of scratching, while in the latter inflammatory symptoms precede the itching.

Treatment. The more acute symptoms are relieved by bathing the parts with a solution of acidum boricum, after which a weak application of acidum carbolicum, either as a lotion or ointment. The late Prof. S. D. Gross recommended the application of the following:—

Ŗ.	Zinci oxidi,		 		• 3 vj	
	Hydrargyri chlor.	corrosiv., .	 	٠	. gr. j	3.6
Sig.	Glycerini, —Apply thoroughl				. 131).	Μ.

Eczema intertrigo. Parts of the body that naturally come into contact with each other, as about the joints, the inner surfaces of the nates, in the groins and beneath the mammæ, are frequently attacked with erythematous eczema, which is frequently, but erroneously, termed erythema intertrigo or chafing. The symptoms are: redness, heat, and a moist, macerated surface, aggravated by movement of the affected parts.

Treatment. The application of a solution of acidum boricum, or the use of dusting powders, such as zinci oleat., amylum, or hydrargyri chloridum mite. It is essential for successful treatment that the opposing surfaces be separated by means of lint or cloths.

Eczema mammarum. The nipples, and more particularly those of primiparæ, are at times the seat of a vesicular eczema, with the formation of crusts and fissures, and unless speedily relieved develops eczema rubrum. The pain on nursing becomes so severe that the mother is compelled to refuse the child. It must be borne in mind that eczema mammarum occurs in women who are not nursing and in single women.

Treatment. Dr. Tilbury Fox advises the following plan:-

"I. Great cleanliness and care in washing away any remnants of milk after each time that the child is put to the breast; and, if the nipple be tender and excoriated, use—

"2. A little liquor plumbi and calamine powder, as follows:-

R.	Liq. plumbi,							f z iss	
	Pulv. calaminæ p	ræp	٠,					3 iss	
	Glycerini,								
	ZXUIDIS					au		. 2 .	ΑU

"3. I cover over the nipple with a lead nipple shield. This excludes the air, keeps the part from being chafed, and I think the lead does good after the part has become less red and sore. I often use a little glyceritum acidi tannici, painted on night and morning.

"The above application can always be removed with a little cold cream and a little warm water sponging before the child goes to the breast."

Eczema palmarum et plantarum. The features of the affection in both these regions are identical. The diagnosis is often obscured by the thickened state of the epidermis. The symptoms are: infiltration, thickening, callosity, moisture followed by dryness, and fissuring, the

last named frequently becoming so deep and painful that the patient is unable to use his hands, or, if on the soles, to walk.

The affection is always chronic, affecting either of the parts alone, or all at one and the same time. Itching is a constant and annoying symptom.

The diagnosis is to be made between eczema of these parts and psoriasis or syphilis.

Treatment. The plan of Hebra for eczema rubrum will usually be successful for this variety. The following formula is also valuable:—

R.	Hydrargyri o	leat.	5-15	per	cent.,		 3 iv	
	Olei cadini,						 3 ss	
	Cerat simp.,						 3 iv.	M.

Sig.—Rub well into part morning and night, first macerating with hot water.

Eczema unguium. The nails are seldom attacked alone, but in connection with eczema manuum. The symptoms are roughness, want of polish, unevenness, and a punctate or honeycomb appearance similar to that seen in psoriasis of the nails. The nail becomes depressed, particularly at its root, thus interfering with its nutrition, resulting in loss of this appendage.

Treatment. Internally, arsenicum is of the greatest value. Locally, the following:—

R.	Ung. picis liq.,				٠						3 iv	
	Hydrargyri chlor. mitis,	٠	٠			۰	۰			٠	3 ss	3.1
Sic	Waselini,	۰	۰	٠	٠	٠	٠	۰	۰	٠	3 iv.	Μ.

It is a remarkable clinical fact, that very many cases of eczema, whether acute, subacute, or chronic, are rapidly cured by the use of *potassii iodidum* in variable doses.

URTICARIA.

Synonyms. Hives; nettle-rash.

Definition. An inflammation of the skin characterized by the development of wheals of a whitish, pinkish, or reddish color, accompanied by stinging, pricking, and tingling sensations.

Causes. Very frequently the result of sudden surface hyperæmia, or rather too rapid circulation through the superficial capillaries, the

result of exposure to heat. Irritants and poison produce an attack when brought in contact with the skin. Gastric, intestinal, hepatic, nephritic, ovarian, uterine, and bladder derangements are very frequent causes. Certain medicaments; malaria; nervous disorders; associated with purpura and rheumatism; pregnancy; lactation; menopause.

Pathology. An acute inflammation of the papillary layer of the skin, characterized by the rapid development of a "wheal"—a more or less firm elevation—consisting of a circumscribed collection of a semi fluid material, the result of a rapid exudation into the upper layers of the skin. The production of the wheal is the immediate result of a disturbance of the vasomotor system, which is shown by the interference of the circulation in the wheal, the blood being driven from its center to its periphery, causing the whitish apex and red areola, so characteristic of the developed wheal.

Symptoms. An attack of "hives" is characterized by the sudden development of *wheals* upon the cutaneous surface, which usually as suddenly disappear, their site being temporarily marked by a spot of redness or hyperæmia.

With the appearance of the wheal occur distressing *itching*, *burning*, *tingling*, *crawling*, *pricking*, and stinging sensations, to relieve which the patient still further irritates, tears, or otherwise wounds the surface by scratching, whence are often developed deep-colored, flat, lenticular papules.

Very frequently an attack of "hives" is associated with fever, headache, and gastric disorder. The "wheals" may appear upon any portion of the body; their size varies from that of a pea to that of a walnut or an egg—the "giant wheals;" the number varying from a very few to being so numerous as to cover the whole surface of the body. The shape, size, color, and number of the wheals that may occur in any given case have given rise to a number of names to designate the lesions. Thus, urticaria annularis occurs in rings; urticaria figurata occurs in spirals; urticaria vesiculosa has a vesicular development on the summit of the wheal; urticaria bullosa, a bullous development at the summit; urticaria papulosa, or lichen urticatus, the wheal and a small papule are combined; urticaria tuberosa, or giant wheals; urticaria hemorrhagica, or purpurata urticaria, a combination of urticaria and purpura; urticaria evanida, a rapid appearance and disappearance of the lesion; urticaria per-

stans, slow disappearance; urticaria conferta, when the wheals are confluent; urticaria pigmentosa, where the wheals are succeeded by pigmentations of the site, the tints varying from dark brown, greenish yellow, to a chocolate color; urticaria febrilis, when the wheals are associated with fever; urticaria ab ingestis, when associated with indigestion.

Treatment. To prevent the recurrence of the disorder, a thorough investigation of the cause must be made, and when found (not always possible) be removed.

Attention should be directed to the state of the general health, the diet, and the secretions.

The following remedies, alone or variously combined, are often of benefit: quinina, pilocarpus, atropina, tinctura belladonnæ, ammonii chloridum, arsenicum, and potassii bromidum. Sodii salicylas, gr. iij-v every two or three hours, often acts like a specific, followed by a thorough purgative. The following pill is valuable in many cases:—

R.	Pulv. pilocarpi,														
	Ext. guiaci, .						āā						gr.	iss	
	Lithii benzoat.,												gr.	iij.	M.
SIC	Two to four ea	-h	£ 53	rer	+ 37	-£	OHE:	he	2111	-6					

If there be atonic dyspepsia and constipation, the following combination is useful:—

R.	Magnesii sulphat., .								
	Ferri sulphat.,						۰		gr. xvj
	Sodii chloridi,								3 ss
	Acidi sulphurici dil.	, .						. 1	[3 ij
	Infus. cascarillæ, .		۰			۰		. 1	ßiv. M.

Sig.—Tablespoonful before breakfast, diluted.

Local measures are of the greatest value, either as baths, lotions, or dusting powders. The following are among the most serviceable: sponging with alcohol, brandy, whiskey, vinegar and water, salt water, alkaline baths, and acid baths. Duhring recommends the following:—

	Acidi carbolici,												
	Glycerini,					٠	٠	٠		٠	٠	fgij	
	Alcoholis,							٠			۰	f Z viij	
	Aq. amygdal. a	ma	r.,	*				٠		٠		f z viij.	M.
~	TT Total				- A	L	 41	 	1.21				

Sig.—Use as a lotion, two or three times daily.

Bulkley suggests the following:-

R. Chloralis,	
Camphoræ,	āāf3j
Misce, and rub and incorporate with	
Pulveris amyli,	
Misce, and keep tightly corked in a v	vide-mouthed bottle.
Sig.—Ruh in with hand	

A serviceable formula is the following:-

R.	Chloroformi, .								
	Ung. zinci oxid.,		٠			٠		ξij.	Μ.
Sig	-Apply with hand								

HERPES.

Definition. An acute inflammation of the skin, characterized by the development of one or more groups of *vesicles*, filled with a clear serum, occurring for the most part about the face (*herpes facialis*) and genitalia (*herpes progenitalis*).

Causes. Herpes facialis; during the course of febrile and nervous disorders; in connection with digestive disorders and colds.

Herpes progenitalis; the origin is local, from uncleanliness or friction.

Pathology. Hebra defines the various forms of herpes as "a series of acute cutaneous diseases of cyclical course, marked by an exudation which collects in drops under the epidermis and elevates it; forming vesicles which are never solitary, but always appear in groups.

Symptoms. The appearance of the vesicles is usually preceded by a feeling of heat in the region, together with slight tumefaction or swelling. Rarely the herpetic attack is attended with malaise and pyrexia.

The eruption usually appears in the form of a small cluster of pinhead to split-pea-sized vesicles, containing a clear fluid, becoming cloudy, afterward puriform, and dries in small, yellowish or brownish crusts; they are few in number and may coalesce. They disappear without leaving a scar.

Herpes facialis; occur upon any portion of the face, but most frequently about the lips—herpes labialis. The alæ of the nose, auricles and the mucous membranes of the mouth and tongue are frequent

locations, in the latter appearing as excoriated patches from rupture of the vesicles.

Herpes progenitalis; in the male the chief site is the prepuce (herpes præputialis). In the female they are comparatively rare; but when occurring it is upon the labia majora and minora and the skin about the vulva.

This variety is preceded by burning, itching, or neuralgic pains, accompanied with redness, congestion, and more or less ædema.

The lesion in these parts is likely to be mistaken for one form or other of venereal disease.

Herpes gestationis; a rare affection of the skin occurring during pregnancy, consisting of erythema, papules, vesicles, and bullæ, attended with intense burning and itching. It may appear at any time of pregnancy up to the seventh month, and continues until some time after delivery.

Treatment. Herpes facialis seldom calls for treatment, although in marked cases of herpes labialis protection with liquor gutta-percha or collodium flexile promotes desiccation.

Herpes progenitalis; cleanliness is of the first importance. Coating the eruption with the medicaments mentioned above or washing with a saturated solution of acidum boricum, and afterward dusting with hydrargyri chloridum mite, are useful.

The parts may be rendered less sensitive in frequently recurring cases by astringent lotions, as *acidum tannicum* or *zinci sulphas*. Circumcision, where required, may be practised.

HERPES ZOSTER.

Synonyms. Zona; shingles; a girdle; intercostal neuralgia.

Definition. An acute, inflammatory disease; characterized by the development of groups of firm and distended vesicles situated upon inflamed bases corresponding to a definite nerve trunk, and accompanied by more or less severe neuralgic pains.

Causes. The eruption and consequent neuralgic pains are the immediate result of an inflammation of the ganglia or of the nerve trunks and branches—a neuritis—probably of the trophic fibres of the affected part; but the cause producing this condition is obscure. Among the many that have been suggested are: cold, injuries to nerves, anæmia, and the medicinal use of arsenicum.

Pathology. An inflammation of either the ganglia, the nerve trunk or branches—probably the trophic system—causing the development of vesicles in the lower strata of the rete, with "the infiltration of serum and inflammatory cells" of the papillæ and corium.

Symptoms. Begins with neuralgic pains, either of the burning or lightning-like character, with slight febrile phenomena, followed by the appearance of papulo-vesicles along the tract of pain; these soon become vesicles situated on bright red, highly-inflamed bases. The vesicles are about the size of pin-heads, or perhaps a little larger, usually discrete, although they frequently coalesce, forming irregular patches, coming in groups until the third to the fifth or even tenth day, when they gradually desiccate, and at the end of the second week nothing remains but a slight scar, which may also disappear after a time or, rarely, is permanent.

When the eruption is at its height it is perfect in its anatomical formation, each vesicle being well-shaped and seated on a bright red, inflamed patch of skin, and distended with a translucent, yellowish fluid.

The eruption is almost invariably confined to one side (unilateral) of the body, although, in rare instances, it is seen upon both (bilateral) sides. It is usually found upon well-known nerve tracts. According to the region affected it is termed zoster capitis, zoster frontalis, zoster faciei, zoster ophthalmicus, zoster auricularis, zoster nuchæ, zoster brachialis, zoster pectoralis, zoster abdominalis, zoster femoralis.

In the very young the eruption may develop and pursue its course without the neuralgic pains.

Diagnosis. The characteristics of herpes zoster or shingles are usually so well marked that an error in diagnosis should not occur. The neuralgic pain preceding the eruption and its development in distinct groups upon inflamed bases following a nerve tract are so different from the simple herpes of the face, or genitalia, or from the lesion of eczema.

Prognosis. Favorable. The affection is self-limited, the duration being about two weeks. It is said that "zoster of the orbital region may seriously involve the eye and prove fatal."

Treatment. The affection being self-limited, it follows that reme-

dies to cut it short are useless. The following combination diminishes the pain and modifies the duration:—

R. Zinci phosphidi,
Ex. nucis vom., gr. x.
M. et ft. pil. No. xxx.
Stg.—One every two to four hours. (BULKLEY.)

Prof. Bartholow "has seen excellent results in cases of shingles from galvanization of the affected intercostal nerves—the positive pole being placed over the point of emergence of the nerves, and the negative brushed over the terminal filaments in the skin."

The general symptoms are to be treated as indicated. Anæmia or depression are benefited by full doses ferri et quininæ citras.

For the pain no remedy seems comparable with the hypodermic use of *morphinæ sulph.*, gr. $\sqrt{s-1/3}$, with *atropinæ sulph.*, gr. $\sqrt{100}$, near the lesion. *Antipyrine*, gr. xv, repeated every three or four hours, or *phenacetin*, gr. v, every three or four hours, relieves the pain in many cases.

Locally, relief follows coating the "shingles" with either collodium flexile or liquor gutta-percha, to which morphine sulphas may be added. Aristol dusted over the parts, or acidum boricum, as a powder, or combined with lanolin, are useful.

MILIARIA.

Synonyms. Lichen tropicus; miliaria rubra; miliaria alba;

prickly heat.

Definition. An acute inflammation of the sweat glands; characterized by the development of discrete, whitish or reddish, pin-point and millet-seed-sized papules, vesicles, or vesiculo-papules, productive of pricking, tingling, and burning sensations of a most aggravated character.

Causes. Excessive heat, the result of excessive or tightly-fitting clothing, or a high external temperature. Most common in fleshy adults who perspire freely, and in children. Nervous prostration; severe dyspepsia and general debility seem to predispose to "prickly heat"

Varieties. Miliaria papulosa; miliaria vesiculosa.

Pathology. The pathology of the two varieties is the same, both

being inflammatory affections of the sweat glands; in the one papules, and in the other vesicles develop about the orifices of the excretory ducts.

In either variety there occurs hyperæmia of the vascular plexus of the sweat gland, followed by slight exudation about the ducts, giving rise to the minute papule or vesicle, which remain until the cause has been modified or removed, when they are rapidly absorbed.

Symptoms. Miliaria papulosa; known as lichen tropicus and "prickly heat," is of sudden onset, with the occurrence of numerous minute, acuminated bright red papules, about the size of a pin head or millet-seed, and but slightly raised above the level of the skin. The papules are preceded by and accompanied with sweating (hyperidrosis), and distressing tingling, pricking, and burning sensations. If the attack be severe, vesico-papules and vesicles are freely interspersed among the numerous papules. Rarely the secretion of sweat is notably diminished.

Miliaria vesiculosa; in this variety, instead of papules, immense numbers of vesicles develop, of the size of pin points and pin heads, of a whitish (miliaria alba) or yellowish-white color. The surface from which they arise is of a bright-red color, owing to each vesicle being surrounded by an areola (miliaria rubra). The vesicles are preceded and accompanied with sweating (hyperidrosis) and most distressing, tingling, pricking, and burning sensations.

Either variety may attack all parts of the body, but the abdomen, chest, back, neck, and arms are the regions usually invaded.

Duration. This varies with the cause. It may appear, fully develop, and disappear in a few hours. In those predisposed, it may continue more or less marked throughout the entire summer.

Diagnosis. If the cause, nature, and seat of the affection are taken into consideration, no error should occur.

Eczema papulosum has a resemblance to "prickly heat," but the course of eczema is slow, and the papules are larger, more elevated, and firmer than those of miliaria papulosa.

Eczema vesiculosum and miliaria vesiculosa are to be differentiated by the marked differences in the progress of each, the former slow, the latter rapid, the vesicles of the former rupturing spontaneously, those of the latter only when severely irritated.

Sudamen is not an inflammatory affection, while miliaria is.

Prognosis. The affection is often most rebellious in fleshy per-

sons and children, and if neglected it passes into eczema or an erythematous intertrigo.

Treatment. The patient should be kept as cool as possible, and avoid undue perspiration. The fears entertained by the laity, of danger from retrocession of the eruption, are groundless; the sooner it disappears the better for the comfort of the patient.

The food should be light and unstimulating, dispensing with meats and condiments for a few days; wine, spirits, and beer are to be

avoided.

The ingestion of water, lemonade, Apollinaris water, Vichy water, together with refrigerant diuretics, as *potassii citras vel acetas*, a cool apartment, and absolute rest will ordinarily insure speedy relief. Saline cathartics are invaluable.

Locally: sponging with alkaline lotions, liquor plumbi subacetatis dilutus, extractum grindeliæ fluidum well diluted, or cupri sulphas, in solution (gr. x, aquæ, fʒj), or acidi carbolici, gr. xx, glyceriti amyli, ʒiij, or a dusting powder, consisting of lycopodium, zinci oxidum, and amylum, singly or combined.

PEMPHIGUS.

Synonym. Water blisters.

Definition. An inflammatory disease of the skin, either acute or chronic, characterized by the development of a succession of rounded, irregular-shaped blebs or bullæ, varying in size from a pea to an egg.

Varieties. Pemphigus vulgaris; pemphigus foliaceus.

Causes. Obscure. It is usually associated with a depressed state of the general system; disorders of menstruation; during pregnancy.

Pathology. Hebra thus describes the appearance of the blebs: "Sometimes a circumscribed, light-red spot appears, perhaps of the size of a bean or a large coin; this is paler in the centre, and may even present a tinge of white, indicating the point at which the bleb is to form, and from which it will spread outward over the surrounding skin, and, in fact, is at first a wheal, passing afterward into a bleb. In other cases the bleb is not preceded either by a red spot or by a wheal, but begins originally as a small collection of clear fluid beneath the cuticle. Thus, hyperæmia of the skin may exist before exudation

is poured out, or the latter may be formed before any congestion of the papillary layer is discoverable."

The contents of the blebs or bullæ are yellowish or colorless serum, of a neutral or alkaline reaction, the older the fluid the more alkaline it becomes. In the late stages of a bleb the fluid becomes puriform. In rare instances blood is contained in the bleb (pemphigus hemorrhagicus).

Symptoms. Pemphigus vulgaris; the onset is slow (pemphigus chronicus), without constitutional symptoms, or acute (pemphigus acutus) preceded by febrile reaction. The lesions are the successive development of blebs, usually from half a dozen to a dozen, varying in size from a pea to an egg, of a round or oval shape, their walls distended with a colorless fluid, the color becoming yellowish or puriform as they grow older. They develop abruptly from the sound skin, with a definite line of demarcation, unattended with symptoms of inflammation. A characteristic phenomena of the lesion is their successive appearance; a crop no sooner disappears than another forms, throughout the course of the affection, each crop running its course in from three to six or ten days. With the appearance of the blebs occur itching and burning, usually of a mild character, although occasionally in a distressing degree (pemphigus pruriginosus).

Pemphigus malignus is characterized by the great size and number of the blebs, which coalesce, rupture and are succeeded by excoriated surfaces which occasionally take on ulcerative action, the patient's health being seriously impaired.

Pemphigus foliaceus differs from pemphigus vulgaris in that the blebs, instead of being distended or tense, are flaccid and only partially filled with fluid, as they rupture before arriving at their state of full development. This variety also appears and disappears in crops. After rupture the fluid immediately dries into thin whitish flakes, which are detached in quantity, leaving a red, excoriated surface—the rete and corium. If the affection has continued for some time, the skin presents the appearance of a superficial scald. The course of this variety is essentially chronic.

All portions of the body are liable to the lesion, as also the mucous membrane of the mouth and vagina. It is most common, however, upon the limbs.

Diagnosis. In a typical case no difficulty should be experienced in making a diagnosis. The mere presence of blebs, however, does

not necessarily constitute pemphigus, for it must be remembered that they are at times developed in other diseases as well as by artificial means; the appearance of blebs in crops is a strong diagnostic point.

Prognosis. The course of the affection is most uncertain, and relapses are frequent. In arriving at an opinion, the occurrence of fatal cases must not be forgotten.

Treatment. Attention to the general health of the patient is of the greatest moment. A careful study of the cause should be made, and if determined, means for its removal are of the first importance.

Two remedies, arsenicum and quinina, are of great value, the secret of success being the persistent use of the former; or if the latter be used, the dose should be large.

Local measures are also of importance. The blebs should be punctured and evacuated as soon as formed. The use of dusting powders of acidum boricum, zincii oxidum, amylum, or violet-powder, or lotions of liquor plumbi subacetatis dilutum, are valuable

Hebra recommends the continuous bath.

IMPETIGO.

Definition. An acute inflammatory disease, characterized by the development of one or more discrete, rounded, and elevated, firm *pustules*, about the size of a pea, unattended with itching.

Causes. Occurs for the most part between the ages of three and ten years, in the well-nourished and healthy. It is not associated with eczema. It is not contagious.

Pathology. The lesion is a well-formed, typical *pustule*, developing abruptly from the surface, containing a whitish-yellow fluid, pus corpuscles, blood corpuscles, epithelial cells, and cellular detritis. The abscess or pustule is about the size of a pea, circumscribed, and superficial.

Synonyms. The affection manifests itself by the development of from one or two to a dozen or more distinct *pustules*, about the size of a split pea, of a rounded shape, raised above the surface, with thick walls, of a yellowish or whitish color, surrounded by a distinct areola, which soon fades, are without a central depression or umbilication, and unattended with either itching or burning.

The affection runs an acute course, usually lasting a couple of weeks. The pustules, after attaining their full size, remain stationary

for a few days, when they disappear by absorption and desiccation, the crusts dropping off, displaying a reddish base, which soon disappears with pigmentation or scar.

The pustules occur on all portions of the body, the most frequent locations being the face, hands, fingers, feet, toes, and lower extremities.

Diagnosis. Impetigo is unassociated with general symptoms, and its particular lesion—the pustule—is discrete, points of importance in the diagnosis.

Eczema pustulosum is also a pustular affection, but the large number, their disposition to coalesce, their location upon an inflammatory base, their rupture and subsequent crusting and itching, are diagnostic points.

The diagnostic points from ecthyma will be pointed out when describing that affection.

Prognosis. Favorable.

Treatment. The pustules should be opened as soon as they mature, the contents removed by washing with tepid water and soap, and the floor covered with hydrargyri chloridum mite or zinci oleat.

Coating the pustules with collodium flexile, or liquor gutta-perchæ, if they are located where irritation be liable, is a valuable mode of

treatment.

ECTHYMA.

Definition. An affection of the skin, characterized by the formation of one or more large, isolated, flat pustules, situated upon an inflammatory base.

Causes. It is most common among those who live in squalor and poverty, and in delicate and poorly-nourished children. Improper and insufficient diet, want of ventilation, excessive work, and uncleanliness are all prominent causes.

Pathology. The lesion is a typical pustular process, severe but superficial, and not extending beyond the papillary layer of the corium. The pustule is situated upon a firm and highly-inflamed base; the number varies from one to a dozen or more.

Symptoms. The disease is characterized by the development of one or more round or oval, yet flat, pustules, about the size of a pea-bean, attended with moderate heat, burning, and pain, and if the number be large, slight febrile reaction. The pustules are first

yellowish in color, surrounded by a firm and sensitive bright-red areola, the pustule afterward becoming reddish from the admixture of blood, soon drying into flat crusts of a brownish color. The duration of each pustule is between two and three weeks, new ones forming, until the cause is removed.

The most prominent sites are the thighs, legs, shoulders, and back. Diagnosis. Ecthyma and eczema pustulosum have points of resemblance, but a study of the clinical history of the latter should prevent error.

Impetigo differs from ecthyma in the size of the pustule and crust. Ecthyma differs from a boil in not having a central core.

Prognosis. With care and the removal of the cause, recovery is always prompt.

Treatment. The general treatment of the patient is of the first importance. Nutritious and wholesome food, cleanliness, bathing, fresh air, and regulated exercise should be advised, together with such tonics as ferrum, arsenicum, quinina, strychnina, and mineral acids.

Locally: remove the crusts by first soaking with oil or fat, or water dressings, and apply—

Pustules showing a sluggish disposition to heal should be stimulated by touching with either argenti nitras, or acidum carbolicum.

FURUNCULUS.

Synonyms. Furunculosis; furuncle; boil.

Definition. An acute affection of the skin, characterized by the occurrence of one or more circumscribed cutaneous or subcutaneous abscesses (boils), which usually terminate by necrosis of the central tissue, its subsequent expulsion in the form of pus or a core, and a resulting cicatrix.

Causes. The result of a depraved condition of the system, induced by general debility, excessive fatigue, nervous depression, improper food and exercise, anæmia, diabetes, uræmia, or the result of local friction, pressure, or contusions.

Pathology. The process resulting in a "boil" has its origin in

either a sebaceous gland, a sweat gland, or a piliary follicle, and never begins in the meshes of the corium. "It begins as a small, roundish spot, which increases in size until certain dimensions are attained, when it undergoes suppurative change, resulting in the formation of a central point or core, composed of the tissue of the gland in which the furuncle originated, which, together with the pus, is cast off. It shows no disposition to become diffuse, being always a circumscribed inflammation. After the discharge of the core, a cavity of more or less depth remains, showing the tissues around it to be hard and infiltrated. After a few days or a week it fills up by granulation, leaving a cicatrix, which is often permanent. The central point or core, when thrown off, is composed of a whitish, tough, pultaceous mass of dead tissue, varying in size with the extent and depth of the inflammation." (Duhring.)

Hydro-adenitis, as seen in the axillæ, around the nipples, and about the anus or perineum, differs from the ordinary "boil" merely in being deeper seated.

Symptoms. "Boils" may occur singly, or more commonly in crops of two, three, or more, another crop following their disappearance (furunculosis).

The abscess begins as a small, rounded, imperfectly defined, isolated, reddish spot, of a highly inflamed character, painful on pressure, its size gradually increasing, its central point presenting evidences of suppuration. It reaches its full development in about a week, when it consists of a slightly raised, rounded, and pointed inflammatory swelling with a yellowish point in the centre—the "core." Abscesses with no central suppuration or core are called "blind boils." The size of a developed boil varies from a split pea to a walnut, the color deep red, with a yellow centre, and is surrounded by a slight areola. The pain of a boil is dull and throbbing, painful on pressure, and is usually worse at night. The constitutional symptoms are mild or severe, according to the number and size of the lesions.

Any portion of the body may be attacked; its preference, however, is for the face, neck, back, axillæ, nipples, buttocks, anus, perineum, and labiæ.

Diagnosis. The characteristics of furuncle are so marked that an error seems impossible. It may be, however, mistaken for carbuncle, the differences between which will be pointed out when discussing that affection.

Prognosis. No danger results from occasional boils, but when occurring in crops they impair the general health and are rebellious to treatment.

Treatment. The treatment of a single boil is well expressed in the word "time." Warm applications are said to hasten the stage of suppuration, and when reached an incision permits the expulsion of the "core," after which the cure soon follows. If the lesion is located where friction or pressure is likely, protection by either covering with adhesive or soap-plaster, smoothly spread, is ample.

When, however, successive crops of boils occur (furunculosis), the treatment should be both constitutional and local. The general health being below par, such tonics as arsenicum, quinina, and ferrum, are of value. Calcii sulphid., gr. $\frac{1}{12}$ - $\frac{1}{8}$, every two or three hours, is valuable in these cases.

Locally, attempts to abort the process may well claim attention, among which are: crucial incisions, to relieve the tension of the central point, will often abate the inflammation and prevent the gangrene; this little operation is rendered painless by the use of the ether spray. Acidum carbolicum, used in five per cent. solution, of which two to five drops injected into the apex of the boil, is valuable. Painting the forming boil with argenti nitras, or tinctura iodi, are also recommended; a paste made by adding together equal parts of glycerinum, and extractum belladonnæ, will often abort a boil; the same is also claimed for unguentum hydrargyri nitratis.

CARBUNCULUS.

Synonyms. Carbuncle; anthrax.

Definition. An indurated, more or less circumscribed, dark red, painful, deep-seated inflammation of the skin and subcutaneous connective tissue, terminating in a slough and the subsequent production of a permanent cicatrix.

Causes. Not positively determined. A deep-seated bruise is a supposed cause. Perhaps, as in furuncle, impairment of the general health is the important factor. It is generally noted to occur in middle life and old age, and in men more frequently than in women. A "specific" cause for anthrax is not an improbable discovery.

Pathology. Although Billroth regards furuncle and carbuncle as differing only in degree, the explanation of Warren, of Boston,

seems the more probable, he being the first to call the attention of histologists " to the existence of small columns of adipose tissue leading from the panniculus adiposus up to the roots of the lanugo hairs, taking an oblique direction in a line with the erectores pilorum. The inflammation resulting in suppuration of the subcutaneous adipose tissue must either form an abscess or become diffuse. In phlegmonous erysipelas the latter condition is observed. But when the inflammation is in the dermoid texture, the exudates infiltrate the skin and naturally follow the canals occupied by the 'columnæ adiposæ.' The pressure thus exerted upon the whole dermoid tissue cannot fail to strangulate the circulation, and thus produce gangrene of the tissue, even if the exudate be not poisonous enough to destroy the cell by its presence. It can, by this explanation, be easily understood why this disease is apt to affect the skin on the nape of the neck and the back more than on other parts of the body. At this point the skin is dense, its fibrous element extending deep into the adipose layer, which is surrounded with strong bands; hence, the pus confined in such a place, seeking the easiest outlet, will travel along these miniature adipose canals, producing the peculiar appearance pathognomonic of carbuncle."

Symptoms. Carbuncle is recognized by its peculiar form; commencing in the lower layers of the cutaneous tissue, it first resembles somewhat a phlegmon minus its bright redness. At first it is somewhat rounded, with a strong tendency to the production of vesicles on its surface, soon, however, becoming firm, circular, and flat, and raised above the surrounding parts, spreading through the subcutaneous tissue and skin, becoming at times enormously large, and having a dark red or violaceous color. As the disease progresses, the pressure results in the softening of the tissues, the skin becoming gangrenous, breaking down at numerous points, forming perforations, through which centres of suppuration appear in different stages of advancement, either as whitish, fibrous plugs, or as cavities, from which a yellowish, sanious fluid oozes, the surface of the anthrax having a cribriform appearance, perforated like a sieve. The entire mass terminates in a slough, which, on being detached, leaves a large, open, deep ulcer, with firm, everted edges, granulating slowly, a permanent cicatrix marking the site of the lesion. The development of the carbuncle is attended with severe pain, of a deep, throbbing, and burning character.

The constitutional symptoms vary with the size, number, and severity of the disease; loss of appetite, coated tongue, general malaise, and moderate febrile reaction accompanies all cases, to which are added those of septicæmia in severe cases.

The duration is from two to six weeks. Its favorite site is the back of the neck, shoulders, back, and buttocks. It is usually single.

Diagnosis. The disease is distinguished from furuncle by its great size, its flat form, its course, the multiple points of suppuration, and the character of the slough. Also by the pain; in furuncle, sensitive and painful to the touch, carbuncle not being particularly sensitive. Furuncles generally occur in numbers or in crops; carbuncle is almost always single.

Prognosis. A guarded opinion should always be given, as death is not infrequent from anthrax, especially in elderly people with impaired health. The mortality, however, is not so great as the laity suppose.

A great danger is septicæmia, from the action of the poison on the blood, or the result of secondary abscesses.

Treatment. Constitutional and local measures are both of the greatest value. Nutritious diet, stimulants, and full doses of such remedies as tinctura ferri chloridi, quininæ sulphas, arsenicum, and ammonii carbonas are beneficial. Good results are reported from calcii sulphid., gr. ½ every two hours.

Locally; the crucial incision, so generally practised in former years, is seldom performed now, the frequent occurrence of hemorrhages being too debilitating. The following are valuable plans:—

Caustic potash, applied to the carbuncle before an opening occurs, until an eschar is fully formed; or, making several small punctures with a scalpel and inserting a small piece of caustic potash well into the diseased tissue; or, if openings have already occurred, insertion of the caustic stick into them, allowing it to remain until melted. By either of these methods I have seen the slough cast off more readily than in cases where the crucial incision was made or in those left to nature. Another method is, "a saturated solution of pure acidum carbolicum is injected through the several apertures in every direction into the sloughing tissues, by the aid of an hypodermic syringe. The pain is severe but short-lived."

Prof. Agnew recommends painting collodium cum cantharide, around the anthrax, in the form of a broad zone, the effect of the

blister being to relieve the tension. *Tinctura iodi*, is also used for a similar purpose. Hebra advocates cloths wrung out in ice water, or ice bags, in the early stage, changing to warm fomentations as soon as suppuration has begun. Dr. Ashhurst has practised with success the use of pressure by means of adhesive plaster applied in much the same manner as for swelled testicle. Success often follows the application of *unguentum hydrargyri nitratis*, spread at least one-eighth of an inch thick and covered with adhesive plaster, changing every twenty-four hours.

The resulting ulcer, after expulsion of the slough, is to be treated on general principles.

ACNE.

Synonyms. Acne vulgaris; acne disseminata; varus; stone-pock.

Definition. An inflammation, usually chronic, of the sebaceous glands; characterized by the development of papules, tubercles or pustules, or by a combination of such lesions, usually in various stages of formation, occurring for the most part upon the face.

Varieties. Acne papulosa; acne pustulosa; acne artificialis.

Causes. Not always understood, as the affection is frequently associated with apparently the most robust health. A frequent cause is puberty. Among the other causes observed are gastro-intestinal disorders, anæmia, chlorosis, uterine disorders, urethral irritation, scrofula, and the use of large doses of the bromides and iodides. Acne may exist alone or be associated with comedo or seborrhæa.

Pathology. An inflammation of the sebaceous gland structure and surrounding tissues. There first occurs retention of the sebaceous secretion, which is soon followed by hyperæmia and exudation about the glands and in the gland wall (acne papulosa), infiltration of the connective tissue (acne tubercula), followed by suppuration (acne pustulosa). If the inflammatory action be severe, destruction of the gland with a resulting cicatrix occurs.

Symptoms. Acne papulosa or acne punctata. This variety of the affection is the earliest stage of the inflammatory action, and is usually of short duration, being soon followed by the development of pus. It is characterized by the occurrence of pin-head to pea-sized, flat, more or less pointed papules, situated about the sebaceous follicles, lightish in color, with a minute central black point, the opening of the

sebaceous duct. Pustules are not infrequently observed scattered among the papules. The lesion is unaccompanied with either local or constitutional symptoms. While the forehead is the most frequent seat for this variety, they sometimes are seen elsewhere,

Acne pustulosa. This is the fully developed affection. It is seen upon the face, neck, shoulders, and back, as pin-head to pea-sized, rounded or acuminated pustules, seated upon an infiltrated, reddish base of superficial or deep inflammatory product (acne indurata). Scattered among the pustules may be seen numerous papules. There are no constitutional symptoms, nor is pain complained of unless the pustule be handled.

Acne artificialis is rather a clinical variety, the result, usually, of large doses of the bromides or iodides, the lesion being identical with acne pustulosa.

Diagnosis. The lesion is so characteristic, the course so chronic, and the location so frequently upon the face, that an error seems impossible if care be exercised.

The resemblance of the papular and pustular syphiloderms must not be mistaken for acne.

Prognosis. Essentially a chronic affection, lasting for a number of years; but if persistent treatment be employed recovery will occur.

Treatment. To successfully combat an attack of acne, both constitutional and local measures must be employed.

Constitutional treatment. The successful treatment of a case of acne depends upon a knowledge of its cause and familiarity with the constitutional habits of the patient. Disorders of digestion and constipution should be corrected. If anæmia be present, ferrum and arsenicum are indicated. Scrofula is an indication for oleum morrhuæ and ferri iodidum. Uterine disorders, if present, should receive proper attention. In young adult males I have seen wonderful improvement follow the passage of a fair-sized bougie once or twice weekly.

Calcii sulphid., gr. $\frac{1}{10}$ - $\frac{1}{2}$, every two or three hours, is valuable in many cases, as is hydrargyri chloridum corrosivum, gr. $\frac{1}{100}$ - $\frac{1}{60}$, three times daily. A remedy highly spoken of by Dr. Bulkley is glycerinum in tablespoonful doses, two or three times daily. Dr. Duhring recommends that it be given in combination with ferri et quininæ citras. Prof. Bartholow "has seen excellent results from the use of syrupus hypophosphitum comp. in acne indurata."

Local treatment. In acne of not very long duration I have seen

excellent results from the following plan: Just before retiring, the parts affected are to be thoroughly washed with water as hot as can possibly be borne, and after the water has partly dried the parts are to be thoroughly covered with *sulphur sublimatum*, applied by means of a powder-puff ball, no rubbing or friction to be employed, and on arising in the morning the sulphur is to be washed off with hot water and the face lightly mopped dry, or what is better, sulphur again applied, if the patient is willing to permit it, during the day.

Dr. Hyde recommends that the contents of the papules and pustules be evacuated by means of a needle, rather encouraging slight bleeding, after which the parts are to be bathed with water as hot as can be tolerated; and while the part is still wet, it is thoroughly scrubbed with *lotio saponis viridis*, then cleansed with water, carefully dried, and anointed with a *sulphur* ointment.

Prof. Bartholow suggested, in a case of *acne indurata* seen with the author, the following successful plan. To dissolve the sebaceous matter—

After which they were anointed with-

Dr. Duhring recommends the use of the following, after washing the parts with hot water:—

 R. Sulphuris præcip.,
 3 j

 Glycerini,
 5 3 ss

 Adipis benz.,
 3 j

 Ol. rosæ,
 gtt. iij.

 Ft. ung.

SIG.—To be thoroughly rubbed into the skin at night.

ACNE ROSACEA.

Synonyms. Gutta rosea; gutta rosacea.

Definition. A chronic hyperæmia or inflammatory affection of the nose and cheeks; characterized by redness, hypertrophy of the skin and dilatation and enlargement of the blood-vessels supplying the part, and the development of more or less acne. The nose and cheeks are the most frequent location.

Causes. Not always determined. It occurs in young women about puberty who are anæmic, or suffer from a general debility, nervous irritability, or prostration, dyspepsia, or menstrual irregularities. It often appears during the menopause. In young males the affection can often be traced to nervous or general debility or dyspepsia. The use of spirituous liquors or of large amounts of condiments are frequent causes, as is constant exposure to the weather. It is frequently associated with seborrhæa.

Pathology. There first occurs blood stasis in the vessels of the part, producing the undue redness first noticed. As a result of the stasis, sooner or later the capillaries are dilated and hypertrophied, and as a result of the interrupted circulation inflammation of the sebaceous gland (acne) results, with the development of papules and pustules. This constitutes the typical acne rosacea. The affection may proceed no further, remaining at this point for years, or, rarely, the pathology of this stage is exaggerated, the involved tissues all hypertrophying, and the connective tissue undergoing a true hyperplasia, causing increased size and abnormal shape of the nose.

Symptoms. The onset of the affection is slow and insidious, characterized at first by more or less diffused redness of the part, the color aggravated by water or cold air. If the nose be the part attacked, it is usually greasy (seborrheic), and is apt to be cool or even cold. This condition may remain for years, but sooner or later the evidence of dilatation and hypertrophy of the capillaries is apparent by the more decided and permanent redness, and upon close examination the enlarged minute cutaneous blood-vessels are seen as delicate or coarse red lines, running superficially over the skin in an irregular and tortuous course. Soon are developed upon the hyperæmic and hypertrophied skin *papules* (acne papulosa) and *pustules* (acne pustulosa), their number never, however, being very great. This constitutes true acne rosacea. The disease may remain in this state, or, rarely, the cutaneous tissues are greatly hypertrophied, the bloodvessels enormously dilated, the glands enlarged, and the connective tissue undergoes hyperplasia, resulting in permanent, dark red, bulky formations, the shape of the nose being contorted into various irregular forms. Duhring reports a case in which the nose was the size of the patient's fist (rhinophyma).

The nose and cheeks are the usual location of the disease, although rarely it involves the forehead.

Diagnosis. The characteristics of the disease are so marked, consisting of rosacea—the dilated and hypertrophic blood-vessels—with papular and pustular acne superadded, that an error can hardly occur if due care be exercised.

Lupus vulgaris bears some resemblance to acne rosacea, as it is apt to develop about the face, and especially the nose; but the papules, tubercles, and pustules of lupus vulgaris soon ulcerate, followed by crusts and cicatrices, which never occur in acne rosacea.

Lupus erythematosus may be confounded with acne rosacea if it occurs upon the end of the nose; but in the former the skin is harsh and covered with adherent whitish and yellowish scales connected with the openings of the sebaceous follicles, which is never the case in acne rosacea.

Frostbite resembles the first stage of acne rosacea, but the history of the two conditions soon determines the diagnosis.

Prognosis. Favorable, if treatment be instituted during the first stage. After hypertrophy has occurred but little can be accomplished.

Treatment. The cause is to be sought after and removed, and the general health to be promoted. The use of all alcoholic drinks is to be interdicted and but small amounts of tea and coffee are to be allowed. In the first stage good results may be obtained from the following formula, known as "Kummerfeld's lotion:"—

	R.	Sulphur præcipitat.,		 	. Ziv	
		Pulv. camphoræ,		 	, gr. x	
		Pulv. tragacanthæ		 	. Äi	
		Aquæ calcis,				
		Aquæ rosæ,				M.
Or—	Sig	-Shake the bottle before using				
Oi ·	R.	Hydrargyri chlor. corrosiv., . Ung. petrolei,		 	gr. ij	М.
	Sig	-Apply thoroughly.		 	· 3)·	IVI.
041	- C-1	la la la Cart	Т			

Or, the following, suggested by G. H. Fox-

₿.	Chrysarobini, Coll o dii,		,	 			3 ss 3 i.	М.
	Dut a bruch							

For the second stage stronger applications are usually required. The dilated capillaries should be incised with a sharp knife, in the hope that adhesive inflammation may close the calibre of the vessels, cold water compresses being used to control the bleeding, a few of the dilated vessels being thus treated every day or two, until all have been incised. Another plan is to paint the affected parts, once or twice a week, with a ten to twenty grain solution of *potassa*, following its application with an emollient poultice. Electrolysis has also been recommended.

In the third stage the knife is the only effectual remedy.

PSORIASIS.

Synonyms. Lepra; alphos; psora; English leprosy.

Definition. A chronic affection of the skin, characterized by reddish, more or less thickened and elevated, dry, inflammatory, and somewhat wrinkled patches, variable as to size, shape, and number, and covered with abundant whitish or grayish-colored, imbricated scales. It is not contagious.

Cause. Not known. The source of the affection is, no doubt, limited to the skin itself, as no external or internal factors can produce it. It occurs in the robust and in the feeble, and in males and females. It usually first appears in early life, and recurs at intervals for years.

Pathology. According to Dr. A. R. Robinson, of New York. "the disease is essentially a hyperplasia of the normal constituents of the Malpighian layer (mucous layer). The increase takes place chiefly in the interpapillary portion of the layer, the growth of which downward causes an apparent increase in the size of the papillæ of the corium, which, however, on closer examination, are found not to be enlarged. In the later stages of the disease the more superficial blood-vessels of the corium become dilated, a more or less considerable emigration of the white blood corpuscles takes place, and the immediate neighborhood of the vessels, together with the connective tissue of the corium, becomes the seat of a round-cell infiltration, which, with the effusion of serum, separates the connective-tissue bundles and fibres into an open meshwork. During the period of disappearance of the disease there is a gradual return to the normal condition, until the hyperplasia, dilatation of the blood-vessels, and cell infiltration have completely disappeared. The hair in psoriasis is affected from the beginning of the disease, hyperplasia of the external root sheath, the structure corresponding to the Malpighian layer of the epidermis, taking place, with extension of the hyperplastic structure into the surrounding cutis. The sebaceous and sweat glands are not at any time affected."

Symptoms. Psoriasis begins as small, *reddish spots*, of the size of a pin's head, which immediately become covered with scanty or abundant *whitish* or *grayish*, *imbricated* scales. The spots gradually increase in diameter, forming patches of various sizes and shapes.

If one of the scales be detached by means of the finger nail, it will be found to adhere quite firmly to the skin, and to be about the thickness of a card-board. If the reddish patch thus made bare be pinched up between the finger and thumb, and compared with a similar pinch of the healthy skin, its inflammatory thickening will be discerned. There is no watery discharge at any time.

The skin between the patches is perfectly healthy.

While the anatomical lesions are always identical, the eruption assumes such features, as to the size and shape of the patches, as to give rise to special names.

Psoriasis functata. The eruption occurs as small, rounded patches, about the size of a pin's head. This is a rare variety, as the lesion rapidly increases in size.

Psoriasis guttata. The eruption occurs in the form and size of drops, and when covered with scales gives the skin the appearance of having been splashed with mortar. A quite frequent variety.

Psoriasis mummularis. The eruption resembles variously sized coins. This is frequently as large as the patches grow.

Psoriasis circinata. The eruption about the size of the former variety, the centre clearing away, leaving the skin normal, although it may continue to enlarge at the periphery, after the manner of tinea circinata.

Psoriasis gyrata. The eruption in wavy lines, of the width of about half an inch, resembling circles and semicircles. This variety is a continuation of the former, from the joining of the patches of psoriasis circinata.

Psoriasis diffusa. The patches of eruption are large and of irregular shape, covering a considerable amount of surface. This variety occurs more frequently on the front of the leg and the outer aspect of the forearm.

Psoriasis palmaris et plantaris. In these regions the eruption is characterized by larger, thicker, and less lustreless scales, and by the occurrence of deep and painful fissures, from which exudes either a serous or sanguineous fluid.

Psoriasis unguium. In psoriasis of the nails they become thickened, opaque, grayish in color, deeply grooved transversely, and often pitted, and in rare cases the nails are replaced by a scaly incrustation.

Any portion of the body is liable to be attacked with psoriasis. The only discomfort the patient suffers is the *itching*, which at times is very severe and distressing.

Diagnosis. A typical case of psoriasis presents no difficulty in diagnosis. There are a few affections, however, which may be confounding in irregular cases.

Eczema squamosum occurring upon the legs closely resembles psoriasis, and if the former has been attended with a very small amount of moisture and the latter has been considerably irritated by scratching, the diagnosis will be very difficult.

 The papulo-squamous syphiloderm and psoriasis are frequently mistaken for each other, the diagnosis at times being extremely difficult.

Tinea circinata and psoriasis circinata resemble each other, but the patches of the latter are less inflammatory, red, and infiltrated, and the scales more abundant and larger than the former. Tinea circinata is usually the result of contagion, and the scales contain a fungus.

Seborrhœa of the scalp and psoriasis of the same region frequently are difficult of diagnosis. In the former the scalp is paler, the scales are finer, smaller, more generally diffused, of a grayish or yellowish color, and greasy, sebaceous character. Psoriasis of the scalp is in patches, which are reddish and infiltrated, and there are almost always patches of the disease on other parts of the body.

Prognosis. An attack can easily be removed, but it is always apt to return, so that a permanent cure can never be promised.

Treatment. Constitutional and local measures are both needed in the majority of attacks of psoriasis.

Constitutional treatment. Attention to the general health, removing all deleterious influences, such as dyspepsia, constipation, lithiasis, malaria, anæmia, or catarrhs.

Among the most valuable remedies used in the treatment of psoriasis is arsenicum, given in full doses for a long period. It is to be borne in mind, however, that the drug is contraindicated in all acute and inflammatory cases. Chrysarobin, gr. 1/8, t. d., gradually increased, has been suggested, but of its utility I have had no experience. Phosphorus, acidum carbolicum, and pix liquida have all been used with variable success.

Local treatment. The character of the local measures should be controlled by the duration of the disease, its extent, location, and obstinacy.

The first step is the thorough removal of the scales. This may be accomplished by repeated washings with soft soap and water, by either plain or alkaline baths, medicated washes, or caustic ointments.

In the early stage, with highly inflammatory symptoms, soothing applications, such as water dressings, or inunctions with oils, of which oleum olivæ rubbed over the patch several times each day is very serviceable.

For chronic cases nothing seems comparable with the following formula, suggested by Dr. G. H. Fox:—

S16.—Rub the chrysarobin with a little alcohol and ether and add to the collodion.

If a camel's hair pencil be placed through the cork, this may be painted over the affected patch after the removal of the scales, and after drying it will not stain the clothing. Care must be exercised that the strength be not too great, or a dermatitis may result.

The following formula I have never seen fail:-

Dr. Bramwell, of Edinburgh, reports remarkable success in the cure of psoriasis, by the internal administration of "a quarter of a raw thyroid gland, finely minced and concealed in rice paper, daily," "and no application whatever was made locally."

Amongst local remedies are: pix liquida, saponis viridis, creasotum, sulphur, calcium sulphuretum, and acidum carbolicum.

HYPERTROPHIES OF THE SKIN.

LENTIGO.

Synonym. Freckles.

Definition. A pigmentary deposit of the skin, characterized by irregularly shaped, pin-head, or pea-sized, yellowish, brownish, or blackish spots, occurring for the most part about the face and back of the hands.

Cause. In the majority of instances exposure to the sun is the exciting cause.

Pathology. In anatomical structure freckles consist of a circumscribed, increased amount of normal pigment, differing from chloasma only in the peculiar form and size of the deposit.

Symptoms. The number of "freckles" varies from a very few to immense numbers. They occur as brownish or yellowish-brown, small, roundish, irregular spots, most commonly upon the face and hands. Rarely the number is very great, and they give to the skin an uncleanly appearance. They are apt to occur at all ages, but rarely before the third year.

They are unattended with itching or other subjective symptoms.

Prognosis. Usually favorable. Their course, when left to themselves, is chronic, lasting for years or a lifetime. They ordinarily appear in the summer, fading away as cold weather approaches, to return the following summer.

Treatment. The following application has been usually successful in my hands:—

R .	Hydrargyri										
	Acid. hydro	ochlo	rici	d1	۱.,	 .*		4		13]	
	Alcoholis,						٠		٠	f $\bar{3}$ j	
	Glycerini,									f 3 ss	
	Aquæ rosæ,					 ad				f \(\tilde{z} \) iv. M.	

Sig.—Apply at bedtime, and remove with soap and water in the morning.

CHLOASMA.

Synonyms. Liver spots; moth.

Definition. A pigmentary discoloration of the skin, characterized by variously-sized and shaped, more or less defined, smooth patches, or of a discoloration, yellowish, brownish, or blackish in color.

Cause. The etiology of chloasma depends upon whether the pigmentation is idiopathic or symptomatic in its occurrence.

Idiopathic chloasma results from the irritation of long-continued scratching, such as is practised in severe eczema or pediculosis, the application of blisters and sinapisms, heat, the direct rays of the sun, and various medicinal and chemical substances, such as follows the prolonged use of argentum (argyria).

Symptomatic chloasma occurs in connection with cancer, malaria, tuberculosis, disease of the supra-renal capsule (Addison's disease), disease of the womb, pregnancy (chloasma uterinum), neurotic disturbances, anæmia, and chlorosis.

Pathology. The affection is an increased deposit of the normal pigment having its seat in the mucous layer of the epidermis. The deposition of the pigment is the result of a nervous derangement, possibly of the trophic system.

Symptoms. Chloasma is simply a discoloration of the skin, unattended with alteration of the surface.

The patches vary in size and shape; they may be as minute as a coin or as large as the hand, or much larger, even to a universal discoloration of the entire surface, and they may be roundish or irregular in outline.

The usual color is yellowish, brownish, or muddy, or even blackish (melasma melanoderma).

In Addison's Disease, of a typical character, "the coloration is brownish, with an olive-greenish or bronze tint, and is general, although, as a rule, especially pronounced upon regions having a disposition to normal increase of pigment, as the face, backs of the hands, axillæ, areolæ of the nipples, and the genital organs; the hair, also, may become darkened. It may, also, occur with or follow other pigmentary changes, as of the hair. Gaskoin reports a case, occurring in a woman aged forty-five, where the patch, situated on the cheek, near the nose, was intensely dark. It had existed nine years. The color of the hair had, fifteen years previously, changed from carrotyred to black." For additional symptoms, see page 180.

In Argyria, or discoloration of the skin resulting from the internal use of nitrate of silver, the color is a bluish, bluish-gray, slate, bronze, or blackish, varying as to the shade. It occurs over the surface generally, but is more pronounced upon parts exposed, as the face and hands.

Chloasma uterinum occurs most frequently between the ages of twenty-five and fifty, seldom after the menopause, caused, in the greater number of instances, by changes, physiological and pathological, which take place in connection with the uterus. It is seen in the married and single, although much commoner in the former. Pregnancy is the most frequent cause, although also associated with either dysmenorrhoea, chlorosis, anæmia, or hysteria.

It is seen in the mildest degree about the eyelids, especially during the menstrual epoch, as a duskiness or swarthiness of the complexion, either lasting a few days or being permanent. As usually encountered, however, chloasma of this variety consists in the presence of one or several patches, appearing generally about the forehead or other parts of the face, upon the trunk, about the nipples, and upon the abdomen. Rarely the entire face is covered with a discoloration, resembling a mask. Cases are recorded in which the pigmentary deposit was general, resembling Addison's disease.

Diagnosis. Tinea versicolor and chloasma resemble each other in the color of the patches, but otherwise they have nothing in common. Tinea versicolor occurs on the trunk, while chloasma occurs upon the face and about the nipples, and in cases the result of pregnancy about the umbilicus, except in those comparatively rare instances in which the discoloration is diffused. The patches of chloasma are smooth, those of tinea versicolor furfuraceous, as can readily be demonstrated by gently scraping the discoloration with the finger nail.

Prognosis. Unless the result of Addison's disease, the prolonged use of argentum, tuberculosis, or cancer, favorable.

Treatment. Chloasma, not the result of organic disease, or the use of argentum, is usually removed by either of the following formulæ:—

	R.	Hydrargyri chloridi corrosiv.,	gr. viiss	
		Zinci sulphat.,	3 ss	
		Plumbi acetatis,		
		Aquæ,	f \(\frac{7}{3} \text{ iv.} \qquad I	M.
	Sig	Lotion. Apply morning and evening.	-HARDY.	
)r				
	R.	Hydrargyri chloridi corrosiv., Acidi acetici dil.,	fʒij Эij	VI.
	Sig	-Lotion. Apply twice dairy.		

Or-

Ŗ.	Hydrarg. ammonia Bismuthi subnit.,							
Stg	Ung. petrolei., .							M.

For argyria, the first step is the withdrawal of the argentum, and, according to Prof. Bartholow, "a persistent and long-continued use of potassii iodidum and sodii hypophosphis has, in a few fortunate instances, caused the absorption and excretion of the silver deposits. The action of these systemic remedies for the discoloration may be aided by baths of the hyposulphites, and by the cautious use of lotions containing potassii cyanidum, which possesses a decided solvent power over the silver deposits.

CALLOSITAS.

Synonyms. Tyloma; callus; callosity.

Definition. Callositas or tyloma consists in the development of a hard or horny, thickened patch of skin, variable in extent, and of a grayish, yellowish, or brownish color, and unattended with pain. The most frequent location is upon the hands and feet.

Causes. The result of pressure or friction, as in the case of the hands of the mechanic, the effect of his tools; or, if upon the foot, the result of ill-fitting shoes or from long marches. Callosities are also seen upon the fingers of violin, banjo, and harp players.

Pathology. A hypertrophy of the horny layer of the skin, the corium remaining normal. The cells of the epidermis become so closely packed together as often to simulate horn substance.

Symptoms. Callositas consists in an increase in the thickness of the skin of the affected part, presenting a firm, dense, more or less circumscribed structure, the extent of hardness varying considerably, sometimes being horny. The patch of hardness is generally about the size of a coin, roundish in shape, and somewhat elevated above the surrounding skin. The color of the patch may be either grayish, yellowish, or brownish.

Callosities are usually upon the palms, fingers, soles, and toes, although other parts, if exposed to the cause, may also be the seat. At times great pain and discomfort are experienced from the growth.

Occasionally callosities are complicated by hyperæmia, fissure, acute

inflammation, abscess, erysipelas, and serve readily as foci for such cutaneous diseases as eczema and psoriasis.

Course. Their formation and development is always slow and gradual. If the cause be removed, the prognosis is favorable.

Treatment. If the removal of the callous growth be desirable, the part should be repeatedly soaked in warm water, or a poultice applied, or warmed oil kept in contact by compresses of flannel, which will soften the induration and permit its removal by paring or scraping, layer by layer, with a sharp knife. Success has been reported from the use of a plaster of india-rubber containing acidum salicylicum.

CLAVUS.

Synonym. Corn.

Definition. A corn is a small, circumscribed, usually flat, deep-seated hypertrophy of the epidermis, having a horny feel, projecting slightly from the skin, painful upon pressure, situated, for the most part, about the toes.

Cause. Continued pressure or friction, usually from ill-fitting or tight boots or shoes.

Pathology. A clavus consists of a circumscribed, excessive hypertrophy of the epidermis, of the same character as occurs in callosity, and of a central portion—the *core*. The core extends deeply into the tissues, in the shape of an inverted cone, the base of the cone being directed outward and appearing upon the surface as a roundish elevation, its apex resting upon the papillary layer of the corium. The core of a clavus consists of a whitish, opaque, firm, tenacious body, composed of epidermic cells, arranged in concentric laminæ.

The pain attending the presence of corns results from pressure upon the true skin by the hard core causing irritation of the nerve filaments of the papillæ.

Corns existing between two toes are constantly bathed with the moisture of the part, which macerates and softens the formation, which thus receives the name of *soft corn*, in contradistinction to the hard corn.

Symptoms. Until the growth attains a considerable size no discomfort, as a rule, is felt. After, however, its depth has reached the true skin, *pain* of an intermittent character, aggravated by pressure, is the chief symptom.

Corns are often weather-sensitive, being unusually painful before, during, or after the occurrence of storms, and should, therefore, not be confounded with gouty or rheumatic deposits below the skin.

Treatment. If freedom from these annoying formations be desired, the use of a properly fitting foot-covering must be practised. The pressure which results in the severe pain is limited by the use of the ringed protective plasters in common use.

To remove the corn, soaking with hot water, or a poultice kept in contact over night, will soften the part and permit of its ready removal with the knife.

For *soft corns*, the application of *argenti nitras*, in solid stick form, is highly spoken of, to be used after the growth has been sufficiently softened

VERRUCA.

Synonym. Wart.

Definition. A wart consists of a circumscribed hypertrophy of the papillary layer, with more or less epidermal accumulation, characterized by the appearance of a hard or soft, rounded, flat, or acuminated formation, of variable size.

Varieties. The following varieties have chiefly a descriptive value: verruca vulgaris; verruca plana; verruca filiformis; verruca digitata; verruca acuminata.

Cause. Obscure. The various assigned causes are probably incapable of producing the affection.

Pathology. While the anatomy of warts differs somewhat according to their variety, in all forms there exist as a basis of their formation a connective-tissue growth, from which the papillary hypertrophy takes place. The interior of the growth is supplied by one or more vascular loops, from which their vitality is obtained.

Symptoms. The various forms are so different as to require a separate description.

Verruca vulgaris, or the ordinary wart, commonly seen on the hands, consists of a small, circumscribed, elevated growth, having a broad base seated securely upon the skin. Their consistency is either soft or firm, the surface smooth or rough, the color that of the surrounding skin, or yellowish, brownish, or even blackish.

They may develop upon any region of the body, but are most commonly seen upon the hands and fingers.

Verruca plana differs from the vulgaris in being flat and broad in form, and but slightly raised above the level of the surrounding skin.

Their most common location is either on the back or forehead.

Verruca filiformis assumes the shape of a minute, thin, conical, or thread-like formation, about an eighth of an inch in length.

The most frequent location is the face, eyelids, and neck.

Verruca digitata consists of a slightly elevated, broad formation, about the size of a split pea, and marked by a number of digitations coming from its border, giving an appearance, in marked cases, resembling a crab.

Their most frequent site is upon the scalp.

Verruca acuminata, known, also, as the pointed wart, the moist wart, the pointed condyloma, cauliflower excrescence, and venereal wart, consists of one or more groups of irregularly-shaped elevations, often so closely packed together as to form a more or less solid mass of vegetations (verrucæ vegetantes). Their color depends somewhat upon the degree of vascularity, varying from a pinkish, bright red to a purple color.

They occur, for the most part, about the genitalia of either sex. Upon the penis, they usually spring from the glans and the inner surface of the prepuce; the inner surface of the labia and from the vagina in the female. They are also seen about the anus, mouth, axillæ, umbilicus, and toes. They may be either moist or dry, according to their location; about the genitalia, a yellowish, puriform secretion usually covers their surface, due to friction and maceration, which, owing to the heat of the parts, rapidly decomposes, producing a highly offensive, penetrating, and disgusting odor.

Their size varies from that of a pea to that of an almond, an egg, or even the fist. Their development is rapid, attaining considerable size in a few weeks.

Prognosis. Favorable.

Treatment. For the smaller warts, excision by means of the knife or scissors affords the most satisfactory results. If the growth be large and likely to be attended with considerable hemorrhage, as in cases of the condyloma about the genitalia, the galvano-caustic wire or the Paquelin cautery are to be preferred. Transfixing the growth in several directions with long needles dipped in a fifty per cent. solution of acidum chromicum has been recommended. The topical application of caustics, such as acidum aceticum, acidum

nitricum, argenti nitras, or ferri perchloridum are often satisfactory. I have been successful in some cases by painting the growth with tinctura thuja occidentalis until their size was considerably reduced, and then snipping them off with the scissors. The following formula for warts and corns is generally sold by pharmacists:—

B .	Acidi salicylici,						٠			3 ss	
	Ext. cannab. indicæ, .				٠	٠	٠			gr. v–x	3.4
	Collodii,			٠	٠	٠		٠	٠	1 3 ss-J.	Μ.
SIC.	Apply once or twice d	ailı	17								

An excellent formula is:-

R. Acidi salicylici,
Acidi boracici, gr. xv.
Hydrargyri chlor. mitis, gr. x. M.
SIG.—Sprinkle over twice daily.

ICHTHYOSIS.

Synonyms. Ichthyosis vera; fish-skin disease.

Definition. Ichthyosis is a congenital, chronic deformity or hypertrophic disease of the skin, characterized by dryness, harshness, or general scaliness of the skin, or in the outgrowth of larger masses of a corneous consistency.

Varieties. Ichthyosis simplex; ichthyosis hystrix.

Cause. Often hereditary, but not in all cases. It is to be regarded as an affection which is born with the individual, although it does not usually manifest itself until after the first or second year of life.

Pathology. "The diseased, or, better, deformed skin is found microscopically to be hypertrophied in various degrees, according to the development of the malady; the proliferation of its elements occurring in the connective tissue, papillæ, stratum corneum, and blood-vessels. In well-marked cases of ichthyosis hystrix, the elongated papillæ are surrounded by dense cones of the horny layer of the epidermis, more or less concentrically disposed, with sclerosis of the connective tissue and a relatively unchanged rete. In this last particular the dense plaque of ichthyosis differs in texture from the wart." (Hyde.)

Symptoms. Ichthyosis displays a wide variation in its symptoms. In one individual it amounts to but a slight inconvenience,

while in another it may manifest itself in so pronounced a manner as to be the source of great discomfort and deformity. The two varieties named represent merely accentuated types of the disorder, rare in its fullest development, and, in its slightest, much more common than is generally believed.

A simple dryness and harshness of the skin, with only slight furfuraceous exfoliation, is termed *xeroderma*.

Ichthyosis simplex is the more common variety, consisting of a harsh, dry condition of the whole surface, accompanied by the production of variously sized and shaped reticulated scales, either small, thin and furfuraceous, like bran, or large and thick, resembling fish scales. Upon the extremities the scales usually form diamond-shaped or polygonal plates, separated from one another by furrows or lines, which extend down to the normal skin. In color the scales are either whitish, grayish, or yellowish, and often have a silvery or glistening appearance. Rarely the color is olive green or blackish (ichthyosis nigricans). The amount of scaling depends upon the age of the patient and the duration and severity of the disease.

Ichthyosis hystrix. With or without the developments of the above variety, in this, the hypertrophy of the skin may occur in circumscribed patches or large areas, consisting of irregularly-shaped, verrucous, corneous, corrugated, wrinkled, or rugous masses, usually darker in color than those of the simple variety. They may occur upon the arms, as solid, warty patches, or upon the back, in the form of elongated, linear patches. They may constitute roughened, corrugated, papillary growths, or uneven, horny, blunt or pointed, spinous, warty formations. In the latter case the elevations may reach several lines or more, and stand out from the skin like quills upon the back of a porcupine—hence the name hystrix. The amount and extent of the hypertrophy varies; the older the patient the more highly developed it will usually be.

Course. Ichthyosis simplex may involve the entire surface uniformly or appear more marked on the extremities, from the hips to the ankles and the arms and forearms. The affection is always worse in winter than in summer, the increased activity of the sweat glands at this season producing the most beneficial results. The course of the affection is essentially chronic, continuing throughout life, now better, now worse. Slight itching usually occurs.

Diagnosis. The characteristics of the affection are so peculiar

that an error in diagnosis is hardly possible. It is to be distinguished from the inflammatory affections of the skin which terminate in desquamation by the absence of any history of inflammation.

Prognosis. While much can be done to alleviate the affection,

the prognosis is unfavorable as regards permanent relief.

Treatment. Local measures are alone of value for ichthyosis. The maceration of the accumulated masses of epithelial hypertrophy is accomplished by water baths, either simple or medicated. The relief thus afforded the patient, while temporary, is comforting. Duhring says: "It may be stated, then, that, as a rule, the more frequently the ichthyotic patient bathes, and the longer he is able to remain in the water, the less will the deformity show itself." Vapor and alkaline baths are also serviceable. Another valuable agent is sapo molis in conjunction with baths, or alone, as a discutient. For severe cases, "a sufficient quantity is to be rubbed into the skin twice daily, for four or six days, during which period the patient is to refrain from bathing. A bath is first to be taken four or five days after the last rubbing, when, in fact, the epidermis has begun to peel off; afterward inunction with a simple ointment is to be applied, in order to prevent fissuring of the new skin.

The following is a useful formula:—

PARASITIC DISEASES OF THE SKIN.

TINEA FAVOSA.

Synonyms. Favus; porrigo favosa; honeycombed ringworm; crusted ringworm.

Definition. A contagious affection of the skin, due to a vegetable parasite—Achorion Schönleinii; characterized by the development of

either discrete or confluent, small, circular, cup-shaped, pale yellow, friable crusts, usually perforated by hairs.

Cause. The presence and growth of a vegetable parasite known as the *Achorion Schönleinii* is the cause of tinea favosa. It is commoner in children than in adults, attacking the former, in the first place, either *de novo* or through direct contagion, and is from them communicated to adults. It is a disease confined almost exclusively to the lower classes.

Pathology. Tinea favosa may have its seat either in the hair follicles and hair, or upon the surface of the skin or the nails; the former, however, are the structures most commonly attacked.

It is purely a local affection, due solely to the presence and growth of the vegetable parasite discovered by Schönlein, of Berlin, in 1839, and named after him—Achorion Schönleinii. The crusts are made up almost entirely of fungus, which is seen, upon section, with the naked eye, to be composed of a porous mass and to possess a pale-yellow or whitish color. Under the microscope it is seen to consist of both mycelium and spores in great quantity and in all stages of development.

Symptoms. When the affection attacks the hairs and follicles it is termed *tinea favosa pilaris*, when the epidermis, *tinea favosa epidermis*, and when the nails, *tinea favosa unguium*. Rarely all the structures may be attacked at one and the same time; its usual seat, however, is the scalp.

The disease begins by the development of one or of several pin-head-sized, pale-yellow crusts, seated about the hair follicles. In about a fortnight these crusts have increased in size and are umbilicated, termed the favus cups, are circumscribed, circular in form, and very slightly elevated above the level of the skin.

In their normal condition they are of a pale-yellow or sulphur-yellow color, but after a time, from dust and other matters, they become brownish- or greenish-yellow in color. The number of crusts vary from a very few to immense numbers. The usual size is about that of a split-pea. In tinea favosa pilaris et capitis the affection is often accompanied with pediculi, while swelling of the glands of the neck and small abscesses upon the scalp are not uncommon. The hairs become lustreless, opaque, brittle, and at times split longitudinally, and from atrophy of the follicles and sebaceous glands permanent baldness may result.

In tinea favosa unguium the nails become thickened, yellow, opaque, and brittle.

The disease has a peculiar odor, resembling that of mice, or of

mustv. stale straw.

Diagnosis. In a recent case the characteristic favus cups, the pale-yellow color, the odor and the history of contagion should render the diagnosis easy. If of long standing, however, and the favi destroyed by scratching, some doubt may exist; but if a small fragment of a crust be placed upon a glass slide with a drop of liquor potasse, covered with a thin glass and placed under a microscope with a power of from two hundred and fifty to five hundred diameters, the features of the Achorion Schönleinii will determine the affection to be tinea favosa.

Prognosis. Tinea favosa of the epidermis readily responds to treatment. Tinea favosa pilaris is more obstinate, and if of long duration may result in baldness.

Treatment. The general health, in the majority of instances, requires tonics. *Oleum morrhuæ*, and *syrupus ferri iodidum*, are invaluable in scrofulous patients. Cleanliness is essential to successful management.

For tinea favosa pilaris et capitis two remedies are essential—parasiticides and depilation. The hair should be cut as short as possible, the crusts removed by the use of oil, or soap and hot water, or poultices, again well oiled and the hairs removed by means of broad-bladed forceps, a few hairs being removed at a time and only a small surface cleared at each sitting, when the following lotion is to be thoroughly applied:—

Ŗ.	Hydrarg. chlorid. corrosiv.,					gr. v-x.	
	Ammonii chlorid. pur., .			٠		3 ss.	
~	Misturæ amygdalæ amar.,					f Z iv.	M.
SIG	.—Apply thoroughly.					-Buli	
							VI.E.Y.

Dr. Shoemaker condemns epilation as injurious to the "hair-follicles and painful to the patient, and should be discarded as a relic of medical barbarism of the last century." He recommends "the application of oleum ergotæ, for twenty-four hours, to soften the crusts, then apply a twenty-five to a fifty per cent. solution of boroglyceride, sponged thoroughly over the affected surface covered with the oil; in

a few hours the crusts will peel off and the surface can be cleaned, when the following powerful antiparasitics should be applied:"—

and then alternate with the following:-

SIG.—Small portion to the affected spots.

"These applications should be made every day or two, and continued for three or four weeks. If, after a cessation of treatment for a week or two, the hair does not assume its natural aspect, and new favus crusts develop, the treatment should be begun afresh."

TINEA CIRCINATA.

Synonyms. Tinea trichophytina corporis; herpes circinatus; ringworm of the body.

Definition. A contagious, parasitic affection of the skin, due to the trichophyton fungus; characterized by the development of one or more circular or irregularly shaped, variously-sized, inflammatory, slightly vesicular or squamous patches, occurring upon the general surface of the body.

Causes. Ringworm of the body is caused by the presence of a vegetable parasite discovered by Bazin, in 1854, termed the trichophyton, the same growth or fungus that produces tinea tonsurans and tinea sycosis. The affection is highly contagious, and is frequently communicated from one member of a family to another, although it has been determined that a certain unknown condition of the skin is requisite for its development. In children it is most frequently seen among the weakly and the poorly nourished. In adults it is usually associated with a decline in the general health.

Pathology. The fungus is seated between the strata of the epidermis, more particularly in the superior layers of the rete. The presence of this foreign body produces the subsequent phenomena—a superficial dermatitis, erythema, exudation, minute vesiculation and

papulation, and, in the severe grades, tubercles and pustules. The desquamative symptoms are exfoliative—nature's efforts for relief.

Symptoms. Tinea circinata varies greatly in the degree of its development, from the trivial complaint so often seen in children, to the chronic, extensive, and obstinate disease sometimes seen about the

thighs in adults (tinea circinata cruris).

The disease usually begins as a small, reddish, scaly, rounded or irregularly-shaped spot of papules, which, in a very few days assumes a circular form (ringworm). It continues to increase in size, the papules often changing to vesicles. A characteristic of the eruption is its healing in the centre as it spreads on the periphery. Occasionally the circles or rings coalesce, forming serpiginous lesions. The usual size of a fully developed ringworm is about that of a silver quarter of a dollar.

Chronic tinea circinata does not present the characteristic annular form, but "are usually in the form of single or multiple, disseminated, small, reddish, slightly scaly, ill-defined spots, on a level with or but slightly raised above the surrounding skin. Not infrequently they are the size of a small or large finger nail, and are irregularly shaped, and, as a rule, without line of demarcation."

The "eczema marginatum" of Hebra is to be looked upon as a severe form of tinea circinata.

Tinea circinata cruris, or ringworm of the thighs, a variety of the "eczema marginatum of Hebra," is usually complicated with true eczema, and is a very obstinate, chronic form of the affection; it is accompanied by severe itching.

Tinea trichophytina unguium is a rare variety. The nails become opaque, whitish, thickened, and soft and brittle, especially along their free border. The microscope is essential for a diagnosis. Its course is chronic, and it is difficult to cure.

Course. As commonly seen, ringworm is very amenable to treatment. Occasionally, however, it exhibits great obstinacy, showing itself repeatedly in the same region, in the form of relapses, or manifesting itself from time to time in new localities.

Diagnosis. Tinea circinata may be mistaken for squamous or other varieties of eczema, but the circular and often annular form, the well-defined margin, the slight desquamation, and the course and history of ringworm should prevent error. Chronic ringworm is more difficult, however.

Seborrhæa and psoriasis often assume a somewhat circular form, and then have a resemblance to ringworm; but a study of the clinical history should render the diagnosis easy.

All doubtful points in diagnosis should be determined by the microscope. The examination can readily be made in the following manner: "A few of the scales may be scraped, with a blunt knife blade, from the suspected patch and placed upon a glass slide containing a drop of liquor potassæ, over which is laid a thin glass cover. The cover should be pressed down and the epidermic mass flattened out. Permitting the specimen to remain for a few minutes, it may be viewed with a power of from two hundred and fifty to five hundred diameters. The fungus will, in most cases, be detected here and there, having at first a faint outline, but becoming more distinct as the specimen stands."

Prognosis. Favorable, as a rule, although the affection is rebellious to treatment in some instances, and prone to relapses.

Treatment. Local treatment is usually all that is required for the cure of tinea circinata. In the majority of instances the following plan will be successful. Washing the patch with soft soap and water and the application of one of the following ointments:—

R Cupri acetat

	ıx.	Ung. aquæ rosæ,	M.
0	Sig	-Keep in contact with the patch.	
Or—		Hydrargyri ammoniat., gr. xx-xxx Ung. petrolei,	М.
Or—	Sig	-Keep in contact with the patch.	
		Hydrargyri chloridi cor., gr. j Tinct. benzoin co., f z̄j. —Apply over eruption.	М.

"In obstinate tinea circinata cruris a saturated solution acidum boricum, applied for a few days, and afterwards cover the parts with the acid in powder, or unguentum hydrargyri ammoniatum.

TINEA TONSURANS.

Synonyms. Tinea trichophytina capitis; herpes tonsurans; ringworm of the scalp.

Definition. A contagious, parasitic affection of the scalp, due to

the trichophyton fungus; characterized by the development of circumscribed, vesicular or squamous, more or less bald patches, showing the hair to be diseased and usually broken off close to the scalp.

Cause. The result of the presence and growth of the same fungus giving rise to tinea circinata—trichophyton. It is an affection of childhood, seldom being seen after puberty. It is highly contagious, and may be communicated from a case of ringworm of the body.

Pathology. The parasite originally named "trichophyton tonsurans" invades the hair, hair follicles, and epidermis of the scalp, the hair, however, suffering the most severely, becoming in a short time filled with the growth to such an extent, usually, as to cause its disintegration and destruction. The hair follicle, also, becomes distended and prominently raised. The hair shaft is fractured just above the level of the scalp, and usually presents a jagged, bristly, stubble-like extremity. The epidermis of the scalp may either present the changes of minute vesicles and desquamation, or, in severe cases, cedema and inflammatory symptoms, with fluid exudation (tinea kerion).

Symptoms. Ringworm of the scalp usually begins in the form of small circumscribed patches, which soon become the seat of small vesicles or pustules, which terminate in desquamation, or of furfuraceous scales. The patches spread rapidly, soon reaching the size of a silver quarter to that of a silver dollar. They are circular in form, circumscribed, of a reddish, grayish, or greenish-yellow color, covered with fine or coarse scales, with the hairs broken off close to the scalp. The epidermis of the scalp is more or less raised, and the follicles are prominent, giving the characteristic appearance of the disease—the goose-skin or plucked-fowl appearance. As a result of the loss of hair, baldness, more or less complete, but temporary, exists.

Itching, slight or severe, is a constant symptom.

Ringworm of the face or body (tinea circinata) may complicate tinea tonsurans.

Chronic ringworm of the scalp is the same condition in a more chronic form, having existed for six months to a year or two.

Tinea kerion is a severe variety of tinea tonsurans, "characterized by œdema, inflammation, and the exudation of a viscid, glutinous, yellowish secretion from the opening of the hair follicles. When fully developed the patches are yellowish, reddish, or purplish in color, and are more or less raised, œdematous, and boggy. They are uneven

and honeycomb-like (hence the name kerion), and studded with yellowish, suppurative points, or, later, with small cavities or foramina, the openings of the distended hair follicles deprived of their hairs, which discharge a mucoid, gummy, honey-like fluid."

The patches are tender, painful, and at times the seat of itching. The course of the affection is chronic.

Diagnosis. The diagnosis is usually unattended with difficulty, if the characteristic circumscribed vesicular or scaly patches with stubby hair be present.

Squamous ezzema somewhat resembles tinea tonsurans, but the hairs are normal in eczema and firmly imbedded in the follicles, while they are almost always stumpy in ringworm, and in those cases in which they are not broken off, if pulled, they easily fall out. Ringworm is contagious, eczema is not.

Alopecia areata presents a white, shiny, ivory-like, bald patch, devoid of scales, eruption, or hair. Ringworm has the vesicular or scaly patch, with broken-off hairs.

In any case of doubt the microscope will readily determine the diagnosis, if "one or two of the short, stumpy hairs should be placed upon a slide with a drop of *liquor potassæ* and permitted to stand a few minutes, when, under a power of two hundred and fifty diameters the fungus, as well as the lesions of the hair, will be visible.

Prognosis. Favorable, although obstinate in chronic cases. Relapses are of frequent occurrence.

Treatment. Local measures are satisfactory in the majority of instances of tinea tonsurans.

Mild cases should be treated by cutting the hair as close as possible and thoroughly scrubbing the patches with sapo viridis and water, or the application twice daily of a twenty-five to a fifty per cent. solution of boroglyceride, or a six per cent. solution of oleatum hydrargyri, or either of the following:—

	R.	Sodii borat., . Aceti destil.,													M.

	Ol. olivæ, .	٠		٠	٠	٠					٠			fgvj.	M.

A preparation very popular in London, known as Coster's paste, is used by painting the patches with a brush and allowing it to remain on until the crust is cast off, in the course of five or six days, when it may be reapplied. A few applications often suffice. Its formula is-

Ŗ.	Iodi,									e			. 3 ^{ij} . f 3 j.	
	Olei	picis,		٠					۰				, f 3 j.	M.
The	iodine	and	oil	of	tar	sho	ould	be	gr	adı	ally	and	slowly mixed.	

An excellent application in rebellious cases is-

R.	Potassæ (caustic)	,							٠	gr. ix	
	Acid carbolici, .				٠	0				gr. xxiv	
	Lanoline,									3 ss	
	Ol. theobromæ,			0	۰		۰			3 ss.	M.
Sig	A small amount									-	If the

scalp is not shaved the application is retained better.

Cases which resist these means are to be treated by removing the loose hairs about the edges of the patches, and the broken-off hairs over the surface, by means of small, broad-bladed, short forceps, a few hairs only being seized at a time; a portion of the diseased hairs to be removed each day until the surface has been cleared. After each depilation, one of the above formulæ is to be applied.

TINEA SYCOSIS.

Synonyms. Tinea trichophytina barbæ; sycosis parasitica; barbers' itch; ringworm of the beard.

Definition. A contagious, parasitic affection of the hair, hairfollicles, and subcutaneous tissues of the hairy portion of the face and neck in the adult male, due to the trichophyton fungus; characterized by the development of tubercles and pustules.

Cause. Tinea sycosis is the result of the presence and growth of

the same vegetable parasite that causes tinea circinata and tinea tonsurans—trichophyton—which invades the hair follicle and hair. It is highly contagious, and is said to be acquired, in most cases, at the hands of the barber (?). It is not a very common affection. Like the other vegetable growths, it seems to require some peculiar, unknown condition of the skin for its development. It may develop from a case of tinea circinata or develop simultaneously with it.

Pathology. The parasite finds its way into the hair follicles and attacks the root and shaft of the hair, causing inflammation, followed by more or less follicular suppuration and general infiltration of the surrounding tissues. The irritation caused by the presence of the fungus results in inflammation of the subcutaneous connective tissue and the well-known tubercular formations peculiar to the affection. They are firm, comparatively painless, and manifest but little disposition to undergo change, remaining during the presence of the fungus and finally gradually disappearing without leaving a scar. Under the microscope the parasite is plainly discernible.

Symptoms. Barbers' itch begins as an attack of tinea circinata—as one or more reddish, scaly patches. Soon the redness and desquamation become more decided, attended with swelling and induration. The hairs will also be dry, brittle, incline to break, and many of them are already loose. The process rapidly increases, the skin becomes distinctly nodular and lumpy, and points of pustulation develop about the openings of the hair follicles. The subcutaneous connective tissue is also involved, giving rise to thick, firm masses of induration.

The surface has a dark red or purplish color, and is studded with variously-sized tubercles and pustules. In some instances the number of tubercles are in excess, while in others the pustules are more numerous, numbers of them discharging, and are succeeded by thick crusts, which are often so abundant as to simulate pustular eczema.

The hairs are always diseased, and break off, either in the follicles or just above the level of the surface. Those not breaking drop out, leaving the region partly or wholly devoid of hair.

The most frequent location attacked is the chin, neck, and submaxillary region. One or, what is more common, both sides of the face are involved.

Itching, burning, pain, and swelling always accompany the affection, varying in intensity from moderate to very severe.

The course of the affection is usually chronic. Relapses are frequent, unless most thoroughly eradicated.

Diagnosis. Sycosis non-parasitica occasions difficulty of diagnosis at times. The points of difference, however, are usually so marked that error should not occur.

Sycosis non-parasitica is a chronic, inflammatory, non-contagious affection of the hair follicles, characterized by the development of papules and pustules, which are perforated with hairs, the hairs themselves being unaffected. The upper lip, cheeks, and chin are the parts mostly involved. If of long duration, some inflammatory thickening results.

In tinea sycosis or sycosis parasitica, the skin and subcutaneous connective tissue are extensively involved, as manifested by the induration and formation of the characteristic tubercles. The upper lip is rarely invaded, the hairs are diseased, broken off, or loose, and under the microscope reveal the parasite.

Pustular eczema resembles tinea sycosis, with extensive pustulation and crusting. But in the former the hairs are not involved, nor are the characteristic tubercles present.

Treatment. Local measures are sufficient for the cure of tinea sycosis. In the majority of instances the following procedure will effect a cure in three or four weeks. If crusts are present, and almost always some are, they are to be thoroughly saturated with inunctions of almond or olive oil, and removed by washing with soft soap and water. The part is then cleanly shaved, the first operation being more painful than subsequent ones. After shaving, the affected surface is bathed for ten minutes in water as hot as can be borne. All pustules are then opened with a fine needle, after which the parts are sponged freely for several minutes with a solution of sodii hyposulphitis, 3j, aqua, f3j, after which the parts are again thoroughly washed with hot water, carefully dried, and smeared with an unquentum sulphur., containing 3j-ij to the ounce. This procedure is preferably performed at night. The following morning the ointment is washed off with soap and water, the face bathed with the sodium solution, and dusted with any inert powder. This plan continued faithfully every night, omitting the shaving when the beard has not grown much, will usually be followed with success.

Cases resisting the above means should, in addition to the above, have the hairs depilated, the shaving performed every two or three

days, thus allowing time for the hairs to grow sufficiently to depilate, the operation seldom being so painful as one would suppose. Shaving and depilation upon alternate days should be faithfully practised until the new hairs show themselves to be healthy.

In addition to the parasiticides mentioned, any of those recommended for the other vegetable parasitic diseases may be used.

TINEA VERSICOLOR.

Synonyms. Pityriasis versicolor; liver-spots.

Definition. A *contagious*, parasitic affection of the skin, due to the *microsporon furfur*: characterized by the occurrence of variously-sized, irregularly-shaped, dry, slightly furfuraceous, yellowish spots upon the chest or other portions of the body.

Cause. Pityriasis versicolor is the result of the presence upon the surface of the skin of a vegetable fungus termed *microsporon furfur*. It is a mildly contagious affection seen after puberty. It is said to occur most frequently in those suffering from wasting diseases, particularly phthisis pulmonalis. It is not connected with any affection of the liver, as supposed by the laity.

Pathology. The fungus permeates the horny layer of the epidermis, never the hair or nail, and gives rise to the irregular-shaped and sized maculæ, of a yellowish or brownish color. As a rule, it gives rise to neither hyperæmia nor inflammatory symptoms.

Symptoms. Tinea versicolor occurs in the form of irregular, roundish, circumscribed, or reticulated maculæ. The spots vary in size from that of a small silver coin to that of the hand. By coalescing they often cover a greater portion of the chest, their most usual site. Upon close inspection the surface of the macule is seen to be covered with furfuraceous scales, and if the scales be not visible, scraping with the finger nail will demonstrate their presence. In color the spots vary from a delicate buff or fawn shade to a yellowish, deep brown, and, rarely, even blackish hue. At times mild itching accompanies the eruption.

Diagnosis. The characteristics of the eruption are so distinct that errors in diagnosis can hardly occur. If any doubt exist, a few of the scales placed upon a glass slide, with a drop of *liquor potassæ*, and covered with a thin glass cover and placed under a microscope

with a power of from two hundred and fifty to five hundred diameters will readily determine the presence of the fungus.

Prognosis. Favorable.

Treatment. The parts should be cleansed with soap and water, and either of the following lotions applied:—

SCABIES.

Synonym. The itch.

Definition. A contagious, animal parasitic disease of the skin, due to the acarus or sarcoptes scabiei; characterized by the formation of cuniculi (burrows), papules, vesicles, and pustules; followed by excoriations, crusts, and general cutaneous inflammation, and accompanied with itching.

Cause. Contagion. The only cause is the presence of the animal parasite, the *acarus*, or *sarcoptes scabiei*. The affection occurs at all ages and in every walk in life.

Pathology. Scabies is an inflammation of the skin with the development of papules, vesicles, pustules, excoriations, and subsequent crusting, the result of the ravages of the animal parasite, together with the irritation produced by the scratching of the patient.

The parasite acarus, or sarcoptes scabiei,—is a minute creature, barely visible to the naked eye as a yellowish-white, rounded body. The female is the most commonly met with, the males being said to take no part in causing the affection, and so are rarely seen. They are said to die in about a week after copulation with the female. The female finds her way by boring through the horny layer into the mucous layer of the epidermis, and, being impregnated, begins at once laying her eggs and at the same time making her burrow. A variable number of eggs are deposited, usually about a dozen, after

which she perishes in the skin. The ova hatch out in eight or ten days.

Symptoms. Scabies being an artificial dermatitis or eczema, according to the amount of irritation produced by the presence of the parasite and the traumatism the result of the severe scratching of the patient.

Immediately upon the arrival of the itch mite upon the skin it begins its work of burrowing, and very soon a burrow or cuniculus is formed, in which the eggs are deposited, and which also becomes the habitat of the female during the remainder of her life. The ova are hatched in about one week after their deposit, and they at once begin to care for themselves and to burrow, resulting in the formation of as many additional cuniculi as there are active female mites. It is the presence of these burrowing parasites that constitutes the irritation resulting in the inflammation of the skin, characterized by the formation of minute papules, vesicles, and pustules, with more or less inflammatory induration. Add to these the excoriations, scratch marks, fissures, torn vesicles, and pustules with yellow and bloody crusts, caused by the scratching, and a picture of the fully-developed disease is seen.

The burrow, or cuniculus, as it is termed, is formed by the mite entering and making its way beneath the horny layer of the epidermis, which is raised, very much as a mole undermines the ground. It occurs as a slight linear elevation of the epidermis, varying from a half a line to four or five lines in length, and having an irregular or tortuous course. Its color is whitish or yellowish, speckled here and there with dark dots. At either end the cuniculus terminates as darkish points, the more prominent of which represent the parasite.

The papules are the first inflammatory lesion, are numerous, and of small size, and may be the extent of the disease.

The vesicles are the next stage, varying in size and number, having an inflamed base, sometimes presenting cunicula upon their summits.

The *pustules* represent the completion of the inflammatory action, their size and number varying with the severity of the irritation.

The *intense itching*, which is worse at night, results in excoriations, torn papules, vesicles, and pustules, followed by crustings, which after a time disguise the characteristic lesions. The regions of the body attacked are the hands, especially the sides of the fingers and the folds where they join the hands. After a time the wrists, penis, and mammæ, and around about and upon the nipples, are invaded.

Persons predisposed to eczema have this affection developed, in addition to the simple dermatitis, by the ravages of the itch mite.

Diagnosis. A case of scabies seen before irritated by scratching presents no difficulty in diagnosis. The presence of the burrows always suffices for the diagnosis, but these are not always discoverable. The location of the eruption always points strongly to scabies. A history of contagion is of value. All doubt can be set at rest by the aid of the microscope.

Prognosis. Always favorable, relapses only occurring when the treatment has been imperfectly carried out or where the individual has re-contracted the disease.

Treatment. Local measures are alone required in the treatment of scabies. The strength of the parasiticides must be controlled by the severity of the inflammatory symptoms present. If eczema complicate scabies, it is to be treated as an ordinary attack after the death of the itch mites

Scabies always succumbs to the following plan. The patient is to be thoroughly washed with soft soap and water, followed by a warm bath, after which one of the following ointments is to be thoroughly rubbed into every portion of the body, special attention being devoted to the hands, fingers, and other parts usually the seat of the disease.

PEDICULOSIS.

Synonyms. Phthiriasis; morbus pedicularis; lousiness.

Definition. A contagious, animal parasitic disease of the head, body, or pubes, due to the presence of pediculi and characterized by

the wounds inflicted by the parasite, together with excoriations and scratch marks.

Varieties. Pediculosis capitis; pediculosis corporis; pediculosis pubis.

Cause. The cause is the presence of the parasite, the result of contagion, direct or indirect. The view of "a spontaneous generation" of pediculi is not accepted by the great majority of observers.

Pathology. The lesion produced by the presence of the pediculi is a minute hemorrhage, caused by the parasite inserting its sucking apparatus, or, as it is termed, its haustellum, into a follicle, and obtaining blood by a process of sucking, and not by biting, as is generally supposed. The presence of the parasite in any great numbers brings about a peculiar irritable state of the skin, which gives rise to an irresistible desire to scratch, as a consequence of which the surface is markedly excoriated and lacerated.

Symptoms. The symptoms which arise from the presence of the parasite in different localities are somewhat different, and call for separate consideration.

Pediculosis capitis. This variety is caused by the presence of the pediculus capitis, or head louse. The ova, or nits, are readily recognized at a distance. Their favorite seat is the occipital region, either upon the surface of the scalp or upon the hair. Their presence gives rise to considerable irritation, itching, and consequent scratching, resulting in the wounding of the scalp, with oozing of a serous or purulent fluid mixed with blood, which soon mats the hair and forms into crusts. In those predisposed to eczema, the presence of the parasite will give rise to that conditon.

The general health is usually unaffected by the presence of the pediculi.

Pediculosis corporis. This variety of the pediculosis is caused by the presence of the pediculus corporis, or body louse, or more properly termed the pediculus vestimenti, or clothes louse. Its color, when devoid of blood, is dirty-white or grayish, with a dark line around the margin of its abdomen. Its habitat is the clothing covering the general surface, remaining upon the skin only long enough to obtain sustenance. The ova are usually deposited in the seams of the clothing, the lice being hatched within the week. Occasionally a few of the pediculi may be observed crawling about the surface, or in the act of drawing blood. As they move over the surface they give rise

to an intensely disagreeable itching sensation, to relieve which the patient scratches, which in turn gives rise to the characteristic lesions of the affection.

The *lesions* are numerous. The scratch marks are scattered here and there, either long and streaked, in other places short and jagged, the excoriations and blood crusts varying in size from a pin head to a split pea or even larger, with irregularly-shaped pustules. In addition to the lesions resulting from the scratching, are seen the *primary* lesions, consisting of minute reddish puncta with slight areolæ, the points at which the parasite has drawn blood. In cases of long standing, a brownish pigmentation of the whole skin may result from the long-continued irritation and scratching. The favorite site of the lesions are the back, especially about the scapular region, the chest, abdomen, hips, and thighs.

Pediculosis is seen most commonly among the poorer classes, and especially the middle-aged and elderly.

Pediculosis pubis. This variety of pediculosis is caused by the presence of the pediculus pubis, or crab louse. Although having its seat of predilection about the pubes, it may also infest the axillæ, sternal region in the male, beard, eyebrows, and even eyelashes.

They may be found crawling about the hairs, but more commonly hugging the surface closely. They infest adults chiefly, and occasion symptoms similar to those described in connection with other species. They are usually contracted through sexual intercourse, although occasionally they are present in cases in which they have not been communicated in this way, and where no explanation as to the mode of contagion can be suggested. The *itching* varies from slight to severe.

Diagnosis. When violent itching exists in any case, without marked eruption, the possibility of the presence of pediculi should always be entertained, and if carefully sought after are found.

Prognosis. Favorable, if the treatment be thoroughly carried out.

Treatment. Local measures alone are all that is necessary for the removal of the various forms of pediculosis.

Pediculosis capitis. The most effective application of this variety is to thoroughly soak the head two or three times a day with ordinary petroleum or kerosene oil, and keep it wrapped in a cloth for twenty-four hours. At the end of this time the head should be thoroughly washed with soft soap and hot water, dried, and saturated with the

official unguentum hydrargyri ammoniati. If required, this entire procedure may be repeated, but usually any pediculi escaping the petroleum are destroyed by the unguentum.

Pediculosis corporis. In this variety, the habitat of the parasite being the clothing, they must be boiled or baked at a temperature sufficiently high to destroy their life. After this the clothing should be changed every day or two, carefully inspected, and if pediculi are seen they must again be baked or boiled. It is folly to expect satisfactory results unless these directions be faithfully adhered to. For the irritation, itching, and excoriations, mild alkaline baths or lotions of acidum carbolicum are sufficient.

Pediculosis pubis. The parts should be washed twice daily with soft soap and water, after which the thorough application of tinctura cocculus indicus, full strength or diluted, or a lotion of hydrargyri chloridum corrosivum or unguentum hydrargyi ammoniati will be effectual.

GOULD'S DICTIONARIES See Page 16.

A NEW SERIES OF STUDENTS' MANUALS

On the various Branches of Medicine and Surgery.

Can be used by Students of any College.

Price of each, Handsome Cloth, \$3.00. Full Leather, \$3.50

The object of this series is to furnish good manuals for the medical student, that will strike the medium between the compend on one hand and the prolix textbook on the other—to contain all that is necessary for the student, without embarrassing him with a flood of theory and involved statements. They have been prepared by well-known men, who have had large experience as teachers and writers, and who are, therefore, well informed as to the needs of the student.

Their mechanical execution is of the best—good type and paper, handsomely illustrated whenever illustrations are of use, and strongly bound in uniform style.

Each book is sold separately at a remarkably low price, and the immediate success of several of the volumes shows that the series has met with popular favor.

No. 1. SURGERY. 318 Illustrations. Third Edition.

A Manual of the Practice of Surgery. By Wm. J. Walsham, M.D., Asst. Surg. to, and Demonstrator of Surg. in, St. Bartholomew's Hospital, London, etc. 318 Illustrations.

Presents the introductory facts in Surgery in clear, precise language, and contains all the latest advances in Pathology, Antiseptics, etc.

"It aims to occupy a position midway between the pretentious manual and the cumbersome System of Surgery, and its general character may be summed up in one word—practical."—The Medical Bulletin.

"Walsham, besides being an excellent surgeon, is a teacher in its best sense, and having had very great experience in the preparation of candidates for examination, and their subsequent professional career, may be relied upon to have carried out his work successfully. Without following out in detail his arrangement, which is excellent, we can at once say that his book is an embodiment of modern ideas neatly strung together, with an amount of careful organization well suited to the candidate, and, indeed, to the practitioner."—British Medical Journal.

Price of each Book, Cloth, \$3.00; Leather, \$3.50.

No. 2. DISEASES OF WOMEN. 150 Illus. NEW EDITION.

The Diseases of Women. Including Diseases of the Bladder and Urethra. By Dr. F. Winckel, Professor of Gynæcology and Director of the Royal University Clinic for Women, in Munich. Second Edition. Revised and Edited by Theophilus Parvin, M.D., Professor of Obstetrics and Diseases of Women and Children in Jefferson Medical College. 150 Engravings, most of which are original.

"The book will be a valuable one to physicians, and a safe and safisfactory one to put into the hands of students. It is issued in a neat and attractive form, and at a very reasonable price."—Boston

Medical and Surgical Journal.

No. 3. ANATOMY. Sixth Edition. 311 ILLUSTRATIONS.

HOLDEN'S ANATOMY. A Manual of the Dissections of the Human Body. By JOHN LANGTON, F. R. C.S., Surgeon to, and Lecturer on Anatomy at, St. Bartholomew's Hospital. Carefully Revised by A. Hewson, M.D., Demonstrator of Anatomy, Jefferson Medical College; Chief of Surgical Clinic, Jefferson Hospital; Mem. Assoc. Amer. Anatomists, etc. 311 Illustrations. This book comes bound in oil-cloth—price \$3.00—as well as in the regular cloth and leather styles.

"The work before us is a brilliant example of the new order of text-books. * * * We would call special attention to the character of the illustrations with which the volume is bountfully furnished."

-American Journal of Medical Sciences.

No. 4. PHYSIOLOGY. Sixth Edition. 254 ILLUSTRATIONS AND A GLOSSARY.

A Manual of Physiology. By GERALD F. YEO, M.D., F.R.C.S., Professor of Physiology in King's College, London. 254 Illustrations and a Glossary of Terms. Sixth American from last English Edition, revised and improved.

This volume was specially prepared to furnish students with a new text-book of Physiology, elementary so far as to avoid theories which have not borne the test of time and such details of methods as are unnecessary for students in our medical colleges.

"The brief examination I have given it was so favorable that I placed it in the list of text-books recommended in the circular of the University Medical College."—Prof. Lewis A. Stimson, M.D., 37 East 33d Street, New York.

Price of each Book, Cloth, \$3.00; Leather, \$3.50.

No. 5. DISEASES OF CHILDREN. SECOND EDITION.

A Manual. By J. F. GOODHART, M.D., Phys. to the Evelina Hospital for Children; Asst. Phys. to Guy's Hospital, London. Second American Edition. Edited and Rearranged by LOUIS STARR, M.D., Clinical Prof. of Dis. of Children in the Hospital of the Univ. of Pennsylvania, and Physician to the Children's Hospital, Phila. Containing many new Prescriptions, a list of over 50 Formulæ, conforming to the U. S. Pharmacopæia, and Directions for making Artificial Human Milk, for the Artificial Digestion of Milk, etc. Illus.

"A safe and reliable guide, and in many ways admirably adapted to the wants of the student and practitioner."—American Journal of Medical Science.

No. 6. MATERIA MEDICA, PHARMACY, PHARMACOLOGY, AND THE-RAPEUTICS.

A Handbook for Students. By WM. HALE WHITE, M.D., F.R.C.P., etc., Physician to, and Lecturer on Materia Medica, Guy's Hospital; Examiner in Materia Medica, Royal College of Physicians, London, etc. American Edition. Revised by REYNOLD W. WILCOX, M.A., M.D., Prof. of Clinical Medicine at the New York Post-Graduate Medical School and Hospital; Assistant Visiting Physician Bellevue Hospital. 580 pages.

Dr. Wilcox's long experience in teaching and writing on therapeutical subjects particularly fits him for the position of editor, and the double authorship has resulted in making a very complete handbook, containing much minor useful information that if prepared by one man might have been overlooked.

No. 7. MEDICAL JURISPRUDENCE AND TOXICOLOGY. THIRD EDITION.

By JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania; President of the Medical Jurisprudence Society of Phila.; Third Edition, Revised and Enlarged.

Price of each Book, Gloth, \$3.00; Leather, \$3.50.

No. 8. DISEASES OF THE EYE. 164 Illus. FOURTH EDITION.

Diseases of the Eye and their Treatment. A Handbook for Physicians and Students. By Henry R. Swanzy, A.M., M.B., F.R.C.S.I., Surgeon to the National Eye and Ear Infirmary; Ophthalmic Surgeon to the Adelaide Hospital, Dublin; Examiner in Ophthalmic Surgery in the Royal University of Ireland. Fourth Edition, Thoroughly Revised. 164 Illustrations and a Zephyr Plate for Testing Color Blindness. 518 pages.

"Mr. Swanzy has succeeded in producing the most intellectually conceived and thoroughly executed resumé of the science within the limits he has assigned himself. As a 'students' handbook,' snall in size and moderate in price, it can hardly be equaled."—Medical News.

"A full, clear, and comprehensive statement of Eye Diseases and their treatment, practical and thorough, and we feel fully justified in commending it to our readers. It is written in a clear and forcible style, presenting in a condensed yet comprehensive form current and modern information that will prove alike beneficial to the student and general practitioner."—Southern Practitioner.

No. 9. MENTAL DISEASES. WITH ILLUSTRATIONS.

Lectures on Mental Diseases, designed for Medical Students and General Practitioners. By Henry Putnam Stearns, A.M., M.D., Physician Superintendent at the Hartford Retreat, Lecturer on Mental Diseases in Yale University, New Haven, Conn., Hon. Mem. British Psycho. Asso'n, etc. With Illustrations and a Digest of the Laws of the various States relating to the Commitment and Care of the Insane. 636 pages.

No. 10. MEDICAL CHEMISTRY. THIRD EDITION, ILLUSTRATED.

A Text-Book of Medical and Pharmaceutical Chemistry. By E. H. Bartley, M.D., Professor of Chemistry and Toxicology at Long Island College Hospital, Chief Chemist Board of Health, Brooklyn, N. Y., etc. With Glossary and Illustrations. 684 pages.

"It is with pleasure that we notice what is probably the best chemistry for medical students—for its size—now in the market. Prof. Bartley has written the book because he had something to say; and he has said it well."—The Journal of the American Medical Association, Chicago, Ill.

Price of each Book, Cloth, \$3.00; Leather, \$3.50.

ANATOMY.

Morris' New Text-Book on Anatomy. Nov Ready. By ten leading Surgeons and Anatomists, and Edited by Henry Morris, F.R.C.S. 791 Specially Engraved Illustrations, 214 of which are printed in colors. Octavo. 1280 pages.

Price in Cloth, 7.50; Sheep, 8.50; Half Russia, 9.50
*** Send for Descriptive Circular and Sample Pages.

- Macalister's Human Anatomy. 816 Illustrations. A new Text-book for Students and Practitioners, Systematic and Topographical, including the Embryology, Histology, and Morphology of Man. With special reference to the requirements of Practical Surgery and Medicine. With 816 Illustrations, 400 of which are original. Octavo. Cloth, 7.50; Leather, 8.50
- Ballou's Veterinary Anatomy and Physiology. Illustrated. By Wm. R. Ballou, M.D., Professor of Equine Anatomy at New York College of Veterinary Surgeons. 29 graphic Illustrations. 12mo. Cloth, 1.00; Interleaved for notes, 1.25
- Holden's Dissector. A manual of Dissection of the Human Body. Sixth Edition. Edited by A. Hewson, M.D., Demonstrator of Anatomy at Jefferson Medical College. 31x Illustrations, many of which are new. Oil-cloth, 3.00; Sheep, 3.50
- Holden's Human Osteology. Comprising a Description of the Bones, with Colored Delineations of the Attachments of the Muscles. The General and Microscopical Structure of Bone and its Development. With Lithographic Plates and Numerous Illustrations. Seventh Edition. 8vo. Cloth, 6.00
- Holden's Landmarks, Medical and Surgical. 4th Ed. Clo., 1.25

 Potter's Compend of Anatomy. Fifth Edition. Enlarged.
 16 Lithographic Plates. 117 Illustrations. See page 14.

Cloth, 1.00; Interleaved for Notes, 1.25

CHEMISTRY.

Bartley's Medical and Pharmaceutical Chemistry. Third Edition. Prepared specially for Medical, Pharmaceutical, and Dental Students. 60 Illustrations, Plate of Absorption Spectra, and Glossary. Revised and Enlarged. Cloth, 3.00

Trimble. Practical and Analytical Chemistry. A Course in Chemical Analysis, by Henry Trimble, Prof. of Analytical Chemistry in the Phila. College of Pharmacy. Illustrated. Fourth Edition, Enlarged. 8vo. Cloth, 1.50

Bloxam's Chemistry, Inorganic and Organic, with Experiments.

Seventh Edition. 281 Illustrations. Cloth, 4.50; Leather, 5.50

**See pages 2 to 5 for list of Students' Manuals.

Chemistry :- Continued.

Richter's Inorganic Chemistry. Fourth American, from Sixth German Edition. Translated by Prof. Edgar F. Smith, PH.D. 89 Wood Engravings and Colored Plate of Spectra. Cloth, 2.00

Richter's Organic Chemistry, or Chemistry of the Carbon Compounds. Illustrated. Second Edition. Cloth. 4.50

Symonds. Manual of Chemistry, for the special use of Medical Students. By Brandreth Symonds, A.M., M.D., Asst. Physician Roosevelt Hospital, Out-Patient Department; Attending Physician Northwestern Dispensary, New York. Cloth, 2.00 Leffmann's Compend of Medical Chemistry. Including

Leffmann's Compend of Medical Chemistry. Including Urinary Analysis. Third Edition. Revised.

See page 15. Cloth, 1.00; Interleaved for Notes, 1.25

Muter. Practical and Analytical Chemistry. Fourth Edition. Revised, to meet the requirements of American Medical Colleges, by Prof. C. C. Hamilton. Illustrated. Cloth, r.25

Holland. The Urine, Common Poisons, and Milk Analysis, Chemical and Microscopical. For Laboratory Use. Fourth Edition, Enlarged. Illustrated. Cloth, 1.00

Woody. Essentials of Chemistry for the Medical Student.
Third Edition. Cloth, 1.25

CHILDREN.

Goodhart and Starr. The Diseases of Children. Second Edition. By J. F. Goodhart, M.D., Physician to the Evelina Hospital for Children; Assistant Physician to Guy's Hospital, London. Revised and Edited by Louis Starr, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania; Physician to the Children's Hospital, Philadelphia. Containing many Prescriptions and Formulæ, conforming to the U. S. Pharmacopæia, Directions for making Artificial Human Milk, for the Artificial Digestion of Milk, etc. Illustrated.

Hatfield. Diseases of Children. By M. P. Hatfield, M.D., Professor of Diseases of Children, Chicago Medical College. Colored Plate. 12mo. Cloth, 1.00; Interleaved, 1.25

Starr. Diseases of the Digestive Organs in Infancy and Childhood. With chapters on the Investigation of Disease, and on the General Management of Children. By Louis Starr, M.D., Clinical Professor of Diseases of Children in the University of Pennsylvania. Illus. Second Edition. Cloth, 2.25

See pages 14 and 15 for list of ? Ouiz-Componds?

DENTISTRY.

Fillebrown, Operative Dentistry. 330 Illus. Cloth, 2.50 Flagg's Plastics and Plastic Filling. 4th Ed. Cloth. 4.00 Gorgas. Dental Medicine. Fourth Edition. Cloth, 3.50 Harris. Principles and Practice of Dentistry. Including Anatomy, Physiology, Pathology, Therapeutics, Dental Surgery and Mechanism. Twelfth Edition. Revised and enlarged by Professor Gorgas. 1028 Illustrations. Cloth, 7.00; Leather, 8.00 Richardson's Mechanical Dentistry. Sixth Edition. By Cloth, 4.50: Leather, 5.50 Warren, 600 Illustrations, 8vo. Sewill. Dental Surgery. 200 Illustrations. 3d Ed. Clo., 3.00 Taft's Operative Dentistry. Dental Students and Practitioners. Fourth Edition. 100 Illustrations. Cloth, 4.25; Leather, 5.00 Talbot. Irregularities of the Teeth, and their Treatment. Illustrated. 8vo. Second Edition. Cloth, 3.00 Tomes' Dental Anatomy. Third Ed. 191 Illus. Cloth, 4.00 Tomes' Dental Surgery. 3d Edition. 292 Illus. Cloth, 5.00 Warren. Compend of Dental Pathology and Dental Medicine. Illustrated, 2d Ed. Cloth. 1.00: Interleaved, 1.25

DICTIONARIES.

Gould's Student's Medical Dictionary. Containing the Definition and Pronunciation of all words in Medicine, with many useful Tables, etc.

½ Dark Leather, 3.25; ½ Mor., Thumb Index, 4.25 Gould's Pocket Dictionary. 12,000 Medical Words Pronounced and Defined. Containing many Tables and an Elaborate Dose List. Thin 64mo.

Leather, gilt edges, 1.00; with Thumb Index, 1.25
Harris' Dictionary of Dentistry. Fifth Edition. Completely revised by Prof. Gorgas. Cloth, 5.00; Leather, 6.00
Cleaveland's Pronouncing Pocket Medical Lexicon. Small pocket size. Cloth, red edges .75; pocket-book style, 1.00
Longley's Pocket Dictionary. The Student's Medical Lexicon, giving Definition and Pronunciation, with an Appendix giving Abbreviations used in Prescriptions, Metric Scale of Doses, etc.

EYE.

Cloth, 1.00; pocket-book style, 1.25

Hartridge on Refraction. 5th Edition. Illus. Cloth, 2.00 Swanzy. Diseases of the Eye and their Treatment. 176 Illustrations. Fourth Edition. Cloth, 3 00; Leather, 3.50 Fox and Gould. Compend of Diseases of the Eye and Refraction. 2d Ed. Enlarged. 71 Illus. 39 Formulæ. Cloth, 1.00; Interleaved for Notes, 1.25

See pages 2 to 5 for list of Students' Manuals.

ELECTRICITY.

Bigelow. Plain Talks on Medical Electricity.

Mason's Compend of Medical Electricity.

Steavenson and Jones. Medical Electricity.

Handbook. Just Ready. Illustrated. 12mo.

Cloth, 2.50

Cloth, 2.50

HYGIENE.

Coplin and Bevan. Practical Hygiene. By W. M. L. Coplin, Adjunct Professor of Hygiene, Jefferson Medical College, Philadelphia, and Dr. D. Bevan. Illustrated. Cloth, 4.00

Parkes' (Ed. A.) Practical Hygiene. Seventh Edition, enlarged. Illustrated. 8vo. Cloth, 4.50

Parkes' (L. C.) Manual of Hygiene and Public Health. Second Edition. 12mo. Cloth, 2.50

Wilson's Handbook of Hygiene and Sanitary Science.

Seventh Edition. Revised and Illustrated. Cloth, 3.25

MATERIA MEDICA AND THERAPEUTICS.

Potter's Compend of Materia Medica, Therapeutics, and Prescription Writing. Fifth Edition, revised and improved. See page 15. Cloth, 1.00; Interleaved for Notes, 1.25

Davis. Essentials of Materia Medica and Prescription Writing. By J. Aubrey Davis, M.D., Demonstrator of Obstetrics and Quiz-Master on Materia Medica, University of Pennsylvania. 12mo. Interleaved.

Net, 1.50

Biddle's Materia Medica. Twelfth Edition. By the late
John B. Biddle, M.D. Revised by Clement Biddle, M.D. 8vo.
Illustrated. Cloth, 4.25; Leather, 5.00

Potter. Handbook of Materia Medica, Pharmacy, and Therapeutics. Including Action of Medicines, Special Therapeutics, Pharmacology, etc. By Saml. O. L. Potter, M.D., M.R.C.P. (Lond.), Professor of the Practice of Medicine in Cooper Medical College, San Francisco. Fourth Revised and Enlarged Edition. 776 pages. 8vo. Cloth, 4.00; Leather, 5.00

Sayre. Organic Materia Medica and Pharmacognosy.

A Handbook of Pharmacy and Medicine. By L. E. Sayre, PH.G., Professor of Pharmacy and Materia Medica, University of Kansas; Member Committee of Revision of U. S. P. 400

Nearly Ready.

See pages 14 and 15 for list of ? Quiz-Compends?

White and Wilcox. Materia Medica, Pharmacy, Pharmacology, and Therapeutics. A Handbook for Students. By Wm. Hale White, M.D., F.R.C.P., etc., Physician to and Lecturer on Materia Medica, Guy's Hospital. Revised by Reynold W. Wilcox, M.D., Professor of Clinical Medicine at the New York Post Graduate Medical School, Assistant Physician Bellevue Hospital, etc. American Edition. Clo., 3.00; Lea., 3.50

MEDICAL JURISPRUDENCE.

Reese. A Text-book of Medical Jurisprudence and Toxicology. By John J. Reese, M.D., Prof. of Medical Jurisprudence and Toxicology in the Medical Depart., University of Pennsylvania. Third Edition. Cloth, 3.00; Leather, 3.50

NERVOUS DISEASES.

Gowers. Manual of Diseases of the Nervous System. A Complete Text-book. By William R. Gowers, M.D., Prof. Clinical Medicine, University College, London. Physician to National Hospital for the Paralyzed and Epileptic. Second Edition. Revised, Enlarged, and in many parts Rewritten. With many new Illustrations. Octavo.

Vol. I. Diseases of the Nerves and Spinal Cord. 616 pages. Cloth, 3.50

Vol. II. Diseases of the Brain and Cranial Nerves. General and Functional Diseases, 1069 pages. Cloth, 4.50

Ormerod. Diseases of Nervous System, Student's Guide to. By J. A. Ormerod, M.D., Oxon., F.R.C.P. (London), Mem. Path., Clin., Ophthal., and Neurological Societies; Phys. to National Hospital for Paralyzed and Epileptic; Dem. of Morbid Anatomy, St. Bartholomew's Hospital, etc. 75 Illustrations. Cloth, 2:00

OBSTETRICS AND GYNÆCOLOGY.

Davis. A Manual of Obstetrics. By Edw. P. Davis, Clinical Lecturer on Obstetrics, Jefferson Medical College, Philadelphia. 16 Plates, and 134 Illustrations. 12mo. 2d Edition. Cloth, 2.50

Byford. Diseases of Women. By W. H. Byford, M.D., Prof. of Gynzeology in Rush Medical College and of Obstetrics in the Woman's Medical College, etc., and H. T. Byford, M.D., Surgeon to the Woman's Hospital, Chicago. Fourth Edition. Enlarged. 306 Illustrations, over 100 of which are original. Octavo. 832 pages. Cloth, 2.00; Leather, 2.50

Lewers' Diseases of Women. A Practical Text-book. 139
Illustrations. Second Edition. Cloth, 2.50

Wells. Compend of Gynæcology. Illustrated. Cloth, r.oo Winckel's Obstetrics. A Text-book on Midwifery, including the Diseases of Childbed. By Dr. F. Winckel, Professor of Gynæcology, University of Munich. Authorized Translation, by J. Clifton Edgar, M.D., Lecturer on Obstetrics, University Medical College, New York. Nearly 200 handsome Illustrations. 8vo. Cloth, 6.00; Leather, 7.00

See pages 2 to 5 for list of New Manuals.

Obstetrics and Gynacology: - Continued.

Parvin's Winckel's Diseases of Women. Second Edition. Including a Section on Diseases of the Bladder and Urethra. 150 Illus. Revised. See page 3. Cloth, 3.00; Leather, 3.50

Landis' Compend of Obstetrics. Illustrated. 5th Edition, Enlarged. By Wells. Cloth, 1,00; Interleaved for Notes, 1,25

PATHOLOGY, HISTOLOGY, ETC.

Stirling. Outlines of Practical Histology. A Manual for Students. 2d Edition. 368 Illustrations. 12mo. Cloth, 3.00

Wethered. Medical Microscopy. By Frank J. Wethered. M.D., M.R.C.P. 98 Illustrations. Cloth, 2.50

Hall. Compend of General Pathology and Morbid Anatomy. 91 very fine Illustrations. Cloth, 1.00; Interleaved, 1.25

Gilliam's Essentials of Pathology. A Handbook for Students. 47 Illustrations. 12mo. Cloth, 75

Virchow's Post-Mortem Examinations. 3d Ed. Cloth, 1.00

PHYSICAL DIAGNOSIS.

Tyson's Student's Handbook of Physical Diagnosis. Illustrated. Second Edition, Enlarged. 12mo. Cloth, 1.50

PHYSIOLOGY.

Yeo's Physiology. Sixth Edition. The most Popular Students' Book. By Gerald F. Yeo, M.D., F.R.C.S., Professor of Physiology in King's College, London. Small Octavo. 254 carefully printed Illustrations. With a Full Glossary and Index. See page 7. Cloth, 3,00; Leather, 3,50

Brubaker's Compend of Physiology, Illustrated. Seventh Edition. Cloth, 1.00; Interleaved for Notes, 1.25

Kirke's Physiology. New 13th Ed. Thoroughly Revised and Enlarged. 502 Illustrations, some of which are printed in colors. (Blakiston's Authorized Edition.) Red Cl., 4.00; Leather, 5.00

Landois' Human Physiology. Including Histology and Microscopical Anatomy, and with special reference to Practical Medicine. Fourth Edition. Translated and Edited by Prof. Striling. 845 Illustrations. Cloth, 7.00; Leather, 8.00

"With this Text-book at his command, no student could fail in his examination."—Lancet.

PRACTICE.

Taylor. Practice of Medicine. A Manual. By Frederick Taylor, M.D., Physician to, and Lecturer on Medicine at, Guy's Hospital, London; Physician to Evelina Hospital for Sick Children, and Examiner in Materia Medica and Pharmaceutical Chemistry, University of London. Cloth, 2:00; Leather, 2:50

See pages 14 and 15 for list of ? Quiz-Compends?

Practice :- Continued.

Roberts' Practice. Revised Edition. A Handbook of the Theory and Practice of Medicine. By Frederick T. Roberts, M.D., M.R.C.P., Professor of Clinical Medicine and Therapeutics in University College Hospital, London. Seventh Edition. Octavo.

Hughes. Compend of the Practice of Medicine. 5th Edition. Two parts, each, Cloth, r.o.; Interleaved for Notes, r.2 Part r.—Continued, Eruptive and Periodical Fevers, Diseases

of the Stomach, Intestines, Peritoneum, Biliary Passages, Liver, Kidneys, etc., and General Diseases, etc.

PART II.—Diseases of the Respiratory System, Circulatory System, and Nervous System; Diseases of the Blood, etc.

Physicians' Edition. Fifth Edition. Including a Section on Skin Diseases, With Index. 1 vol. Full Morocco, Gilt, 2.50

From John A. Robinson, M.D., Assistant to Chair of Clinical Medicine, now Lecturer on Materia Medica, Rush Medical Colleve. Chicago.

lege, Chicago.

"Meets with my hearty approbation as a substitute for the ordinary note books almost universally used by medical students. It is concise, accurate, well arranged, and lucid, . . . just the thing for students to use while studying physical diagnosis and the more practical departments of medicine."

Wythe's Dose and Symptom Book. Containing the Doses and Uses of all the principal Articles of the Materia Medica, etc. Seventeenth Edition. Completely Revised and Rewritten, 32mo. Cloth, 1.00; Pocket-book style, 1.25

PHARMACY.

U. S. Pharmacopœia, 1890, 7th Revision.

Cloth, net, 2 50; Sheep, net, 3.00. (Add 27 cents if to go by mail.)

Sayre. Organic Materia Medica and Pharmacognosy. 400 Illustrations. See page 9. Nearly Ready.

Stewart's Compend of Pharmacy. Based upon Remington's Text-book of Pharmacy. Fourth Edition, Revised in accordance with new U.S P., 1890. Cloth, 1.00; Interleaved for Notes, 1.25

Robinson. Latin Grammar of Pharmacy and Medicine. By H. D. Robinson, PH.D., Professor of Latin Language and Literature, University of Kansas, Lawrence. With an Introduction by L. E. Sayre, PH.G., Professor of Pharmacy in, and Dean of, the Dept. of Pharmacy, University of Kansas. 12mo. Second Edition.

SKIN DISEASES.

Crocker. Diseases of the Skin, their Description, Pathology, Diagnosis, and Treatment, with Special Reference to the Skin Fruptions of Children. By H. Radeliffe Crocker, F.R.C.P., Physician for Diseases of the Skin in University College Hospital. Second Edition. Revised and Enlarged, with 92 Wood-cuts.

Van Harlingen on Skin Diseases. Third Edition. Enlarged and Illustrated. 12mo. In Press.

See pages 2 to 5 for list of New Manuals.

SURGERY AND BANDAGING.

Moullin's Surgery, by Hamilton. 600 Illustrations (some colored), 200 of which are original. Second Edition.

Cloth, net, 7.00; Leather, net, 8.00; Half Russia, net, 9.00

***Complete circulars, with sample pages and Illustrations, free upon application.

Jacobson. Operations in Surgery. A Systematic Handbook for Physicians, Students, and Hospital Surgeons. By W. H. A. Jacobson, B.A. Oxon., F.R.C.S. Eng., Ass't Surgeon Guy's Hospital; Surgeon at Royal Hospital for Children and Women, etc. 199 Illustrations. 1006 pages. 8vo. Cloth. 5.00; Leather, 6.00

Heath's Minor Surgery, and Bandaging. Tenth Edition. 158
Illustrations. 62 Formulæ, and Diet Lists. Cloth, 2.00

Horwitz's Compend of Surgery, Minor Surgery and Bandaging, Amputations, Fractures, Dislocations, Surgical Diseases, and the Latest Antiseptic Rules, etc., with Differential Diagnosis and Treatment. By ORVILLE HORWITZ, B.S., M.D., Demonstrator of Surgery, Jefferson Medical College. 5th Edition, Enlarged and Rearranged. Many new Illustrations and Formulæ, 12mo. Cloth, 1.00; Interleaved for the addition of Notes, 1.25

***The new Section on Bandaging and Surgical Dressings consists of 32 Pages and 41 Illustrations. Every Bandage of any importance is figured. This, with the Section on Ligation of Arteries, forms an ample Text-book for the Surgical Laboratory.

?QUIZ-COMPENDS?

The Best Compends for Students' Use in the Quiz Class, and when Preparing for Examinations.

Compiled in accordance with the latest teachings of prominent Lecturers and the most popular Text-books.

They form a most complete, practical, and exhaustive set of manuals, containing information nowhere else collected in such a condensed, practical shape. Thoroughly up to the times in every respect, containing many new prescriptions and formulæ, and over six hundred illustrations, many of which have been drawn and engraved specially for this series. The authors have had large experience as quiz-masters and attachés of colleges, with exceptional opportunities for noting the most recent advances and methods.

Cloth, each \$1.00. Interleaved for Notes, \$1.25.

25,000 COPIES Of These Books Have Aiready Been Sold.

. 4.1

GOULD'S STUDENT'S MEDICAL DICTIONARY.

Based on Recent Medical Literature.

Small 8vo, Half Morocco, as above, with Thumb Index, . . \$4.25 Plain Dark Leather, without Thumb Index, 3.25

A compact, concise Vocabulary, including all the Words and Phrases used in medicine, with their proper Pronunciation and Definitions.

"One pleasing feature of the book is that the reader can almost invariably find the definition under the word he looks for, without being referred from one place to another, as is too commonly the case in medical dictionaries. The tables of the bacilli, micrococci, leucomaines and ptomaines are excellent, and contain a large amount of information in a limited space. The anatomical tables are also concise and clear. . . We should unhesitatingly recommend this dictionary to our readers, feeling sure that it will prove of much value to them."—American Journal of Medical Science.
